THE STOKES PHENOMENON IN EXACT ASYMPTOTICS

B.L.J. BRAAKSMA, G.K. IMMINK, AND Y. SIBUYA

Dedicated to Prof. H.L. Turrittin on the occasion of his ninetieth birthday

As an introduction we present a new, elementary and constructive proof of the multisummability properties of formal solutions of linear ODE's at irregular singular points. This serves to illustrate the geometric approach to multisummation. Basic properties of multisums and the associated sheaves are derived. Next, we study Cauchy-Heine transforms in relation to multisummation and the Stokes phenomenon. We show how to construct multisums with a prescribed Stokes phenomenon, using the Malgrange-Sibuya isomorphism. Starting from the Stokes automorphisms we introduce the alien derivations of J. Ecalle and derive Ecalle's bridge equation for the general integral of linear ODE's. The main ideas are illustrated with some very simple examples.

Introduction.

Consider the differential equation (D) : $Dy = 0$, where D is a linear differential operator of order n , with coefficients in $\mathbf{C}\{z\}$. It has n independent formal solutions of the form:

$$(1) \quad \hat{y}_l(z) = e^{q_l(z)} z^{\rho_l} \hat{h}_l(z)$$

where $\rho_l \in \mathbf{C}$, $q_l \in z^{-1/p} \mathbf{C}[z^{-1/p}]$, and $\hat{h}_l \in \mathbf{C}[[z^{1/p}]][\log z]$ for some $p \in \mathbf{N}$.

According to the main asymptotic existence theorem (cf. [26]) there exists $\epsilon > 0$ such that for every interval $I \subset \mathbf{R}$ with length $|I| < \epsilon$ and every $l \in \{1, \dots, n\}$, there exists a solution $y_{l,I}$ of (D) with the property that $y_{l,I} \sim \hat{y}_l$ on I , i.e.

$$e^{-q_l(z)} z^{-\rho_l} y_{l,I}(z) \sim \hat{h}_l(z) \text{ as } z \rightarrow 0, \arg z \in I.$$

In general, however, this solution is not unique. The object of exact asymptotics is to associate a unique "sum" with a given divergent power series. For the class of divergent power series arising in the theory of analytic differential equations this can be achieved by means of a process called 'multi-summation'. There exist two, essentially equivalent, approaches to the theory of multi-summability: The analytic approach, which is based on the use of Borel and Laplace transformations, and the geometric approach. In the

latter, an important part is played by so-called (k -precise) quasi-functions: Analytic functions which are defined modulo functions with exponential decrease of some order (k). The term k -precise quasi-function was introduced by J.-P. Ramis in [24]. In this paper, we explain and develop the second approach.

The paper is organized as follows. In §1 we give an elementary and constructive proof of the multi-summability of the formal series \hat{h}_l in (1). This section serves as an introduction to and motivation of the geometric approach. In §2 we derive some basic properties of quasi-functions and multi-sums. §3 deals with Cauchy-Heine transforms in relation to multi-summability and the Stokes phenomenon. Here, also the inverse problem is considered: To construct multi-sums with a prescribed Stokes phenomenon. In §4 we discuss the Stokes phenomenon in a fixed direction. In §5 we introduce Stokes automorphisms and give a definition of the alien derivations of J. Ecalle in terms of quasi-functions. The main ideas are illustrated in two very simple examples of linear differential equations.

1. Introductory example.

We begin by introducing some notation.

Definition 1.1. Let $I \subset \mathbf{R}$ be an open interval. $\mathcal{A}(I)$ is the set of all functions f with the property that, for any closed interval $I' \subset I$, there exists a positive number r such that f is holomorphic on the sector $S(I', r) := \{z : |z| < r, \arg z \in I'\}$ of the Riemann surface of $\log z$. With the natural restriction mapping, the sets $\mathcal{A}(I)$ form the sheaf \mathcal{A} on \mathbf{R} of holomorphic functions in a sector with vertex at O . For any $\theta \in I$, the germ at θ of $f \in \mathcal{A}(I)$ is the equivalence class of functions $f' \in \mathcal{A}(I')$, where $I' \ni \theta$, such that $f'|_{I''} = f|_{I''}$ for some open interval $I'' \subset I \cap I'$ containing θ . This germ is denoted by f_θ . The stalk \mathcal{A}_θ of \mathcal{A} is the set of all germs at θ of functions $f \in \mathcal{A}(I)$, where I is any open interval containing θ .

Let $k > 0$. By $\mathcal{A}^{\leq -k}$, $\mathcal{A}^{< -k}$, $\mathcal{A}^{\leq k}$ and $\mathcal{A}^{< k}$ we denote the sheaves on \mathbf{R} of holomorphic functions with at least exponential decrease of order k , with ‘supra-exponential decrease of order k ’, with at most exponential growth of order k and with ‘subexponential growth of order k ’, respectively, in some sector with vertex at the origin. More precisely, if $I \subset \mathbf{R}$ is an open interval, $\mathcal{A}^{\leq -k}(I)$, $\mathcal{A}^{< -k}(I)$, $\mathcal{A}^{\leq k}(I)$ and $\mathcal{A}^{< k}(I)$ are the sets of all functions f with the property that, for any closed interval $I' \subset I$, there exists a positive number r such that f is holomorphic on the sector $S(I', r) := \{z : |z| < r, \arg z \in I'\}$ of the Riemann surface of $\log z$, and

$$\sup_{z \in S(I', r)} |f(z)| e^{c|z|^{-k}} < \infty$$

for some $c > 0$, for all $c > 0$, for some $c < 0$ and for all $c < 0$, respectively.

We consider the differential equation (D) with formal solutions (1). For $l, m \in \{1, \dots, n\}$, let $q_{ml} = q_m - q_l$. If $q_l \not\equiv q_m$, there exist $\kappa_{ml} \in \frac{1}{p}\mathbf{N}$ and $\omega_{ml} \in \mathbf{C}^*$ such that

$$q_{ml}(z) = \omega_{ml} z^{-\kappa_{ml}} + o(z^{-\kappa_{ml}}).$$

Definition 1.2. The numbers κ_{ml} are called the **levels** of the differential equation (D) . We say that $m \prec l$ on the interval I if $e^{q_{ml}(z)}$ decreases exponentially of order κ_{ml} as $z \rightarrow 0$, $\arg z \in I$ (so if $\cos(\arg \omega_{ml} - \kappa_{ml}\theta) < 0$ if $\theta \in I$). θ is a **Stokes direction of level** κ_{ml} for the pair (m, l) if $\cos(\arg \omega_{ml} - \kappa_{ml}\theta) = 0$. Let the increasing sequence of Stokes directions be denoted by $\{\theta_h\}_{h \in \mathbf{Z}}$. If $m \prec l$ on an interval $(\theta_\sigma, \theta_\mu)$ of length π/κ_{ml} then $\{\theta_\sigma, \theta_\mu\}$ is called a $(m \prec l)$ -**Stokes pair** or a **Stokes pair of level** κ_{ml} and we denote θ_μ by θ_{ml} . If $I_j, j = 1, \dots, r$, are open intervals such that $I_r \subset I_{r-1} \subset \dots \subset I_1$ then (I_1, \dots, I_r) will be called a **nested multi-interval**. If I and $I^{(\nu)}, \nu = M, \dots, N$, are open intervals where M and N are integers such that $M < N$, $\cup_{\nu=M}^N I^{(\nu)} = I$ and $I^{(\nu)} \cap I^{(\mu)} \neq \emptyset$ iff $|\nu - \mu| \leq 1$ then $\{I^{(\nu)}\}_{\nu=M}^N$ is called a **finite covering** of I .

Suppose that (D) has r distinct levels: k_1, \dots, k_r in order of increasing magnitude. It is known that one can associate a unique sum to \hat{y}_l and any nested multi-interval (I_1, \dots, I_r) , if $|I_j| > \pi/k_j$ and I_j does not contain Stokes pairs of level k_j (cf. [22], [2], [5], [21]). Here we give another proof of this property based on the main asymptotic existence theorem mentioned above. Another proof based on this theorem has been given by M. van der Put (to appear). Similar ideas can be found in B. Malgrange [19]. From the main asymptotic existence theorem we first derive a fundamental system of normalized solutions, due in the generic case to G.D. Birkhoff [3] and in the general case to W. Balser, W.B. Jurkat and D.A. Lutz (cf. [13, p. 85]).

Lemma 1.3. *Let $l \in \{1, \dots, n\}, \nu_0 \in \mathbf{Z}$. Then there exist solutions $\{y_l^{(\nu)}\}_{\nu \in \mathbf{Z}}$ of (D) such that $y_l^{(\nu)} \sim \hat{y}_l$ on $(\theta_{\nu-1}, \theta_{\nu+1})$ and*

$$(2) \quad y_l^{(\nu)} - y_l^{(\nu-1)} = \sum_{\theta_{hl}=\theta_\nu} \alpha_h(l, \nu) y_h^{(\nu-1)} \quad \text{if } \nu > \nu_0,$$

$$(3) \quad y_l^{(\nu)} - y_l^{(\nu-1)} = \sum_{\theta_{lh}=\theta_{\nu-1}} \alpha_h(l, \nu) y_h^{(\nu)} \quad \text{if } \nu \leq \nu_0.$$

Proof. Let $I := (a, b)$ be an interval that contains a Stokes direction θ_ν and with $|I| < \epsilon$ as in the Introduction. Then it is well known and easy to see that $y_{l,I} \sim \hat{y}_l$ on $(\theta_{\nu-1}, \theta_{\nu+1})$. Denote $y_{l,I}$ by $\tilde{y}_l^{(\nu)}$.

Let $y_l^{(\nu_0)} := \tilde{y}_l^{(\nu_0)}$ for $l = 1, \dots, n$. Let $\nu \geq \nu_0 + 1$ and suppose the construction of $y_l^{(\nu)}$ satisfying (2) has been performed up to $\nu - 1$. Let

$I = (\theta_{\nu-1}, \theta_{\nu+1})$. Then there exist constants b_h such that

$$\tilde{y}_l^{(\nu)} - y_l^{(\nu-1)} = \sum_{\theta_{hl}=\theta_\nu} b_h y_h^{(\nu-1)} + \sum_{h \prec l \text{ on } I} b_h \tilde{y}_h^{(\nu)},$$

since the solutions $y_h^{(\nu-1)}$ with $\theta_{hl} = \theta_\nu$ and $\tilde{y}_h^{(\nu)}$ with $h \prec l$ on I can be extended to a fundamental system by solutions $\tilde{y}_h^{(\nu)}$ which dominate the lefthand side on $(\theta_{\nu-1}, \theta_\nu)$. Therefore we choose

$$y_l^{(\nu)} = \tilde{y}_l^{(\nu)} - \sum_{h \prec l \text{ on } I} b_h \tilde{y}_h^{(\nu)} = y_l^{(\nu-1)} + \sum_{\theta_{hl}=\theta_\nu} b_h y_h^{(\nu-1)},$$

so that $y_l^{(\nu)} \sim \hat{y}_l$ on I and (2) holds up to ν . Thus we recursively obtain all $y_l^{(\nu)}$ with $\nu \geq \nu_0$. Similarly the case with $\nu < \nu_0$ can be handled. \square

From this lemma we deduce:

Theorem 1.4. *Let $l \in \{1, \dots, n\}$ and (I_1, \dots, I_r) be a nested multi-interval such that $|I_j| > \pi/k_j$ and I_j does not contain any $(h \prec l)$ -Stokes pair of level $\kappa_{hl} = k_j$ for $j = 1, \dots, r$. Let $k_{r+1} := \infty$. Then there exist a finite covering $\{I^{(\nu)}\}$ of I_1 and solutions $w_l^{(\nu)}$ of (D) such that the endpoints of all I_j belong to the set of endpoints of all $I^{(\nu)}$ and such that*

$$(4) \quad w_l^{(\nu)} \sim \hat{y}_l \text{ on } I^{(\nu)},$$

$$(5) \quad e^{-q_l} \left(w_l^{(\nu)} - w_l^{(\nu-1)} \right) \in \mathcal{A}^{\leq -k_{j+1}} \left(I^{(\nu-1)} \cap I^{(\nu)} \right) \text{ if } I^{(\nu-1)} \cup I^{(\nu)} \subset I_j.$$

Thus $e^{-q_l} \left\{ w_l^{(\nu)} \right\}_{I^{(\nu)} \subset I_j}$ defines an element

$$(6) \quad e^{-q_l} w_{lj} \in \mathcal{A} / \mathcal{A}^{\leq -k_{j+1}}(I_j) \text{ with } e^{-q_l} w_{lj} \pmod{\mathcal{A}^{\leq -k_j}} = e^{-q_l} w_{l,j-1}|_{I_j}.$$

Moreover, if $j \in \{1, \dots, r\}$ then w_{lj} is uniquely determined by \hat{y}_l and the multi-interval (I_1, \dots, I_j) . In particular, w_{lr} is an ordinary function which is a uniquely determined solution of (D) on I_r .

Proof. It is sufficient to give the proof for the case that the intervals I_j have Stokes directions as endpoints since otherwise we can enlarge I_j to such intervals with the other assumptions remaining satisfied. Let $I_j = (a_j, b_j)$, $j = 1, \dots, r$ and $I^{(\nu)} := (\theta_{\nu-1}, \theta_{\nu+1})$, $\nu \in \mathbf{Z}$. We use Lemma 1.3 with $\nu > \nu_0$ where $\theta_{\nu_0} < a_1$. Let the linear operator $M_j^{(\nu)}$ on the solution space of (D) be defined by

$$(7) \quad M_j^{(\nu)} y_m^{(\nu)} = y_m^{(\nu-1)} + \sum_{\theta_{hm}=\theta_\nu, \kappa_{hm} \leq k_j} \alpha_h(m, \nu) y_h^{(\nu-1)}, m = 1, \dots, n,$$

except if

$$(8) \quad \theta_{\nu-1} = a_p \in I_j \text{ (so } p > j) \text{ and } \kappa_{ml} = k_p, m \prec l \text{ on } I^{(\nu)}$$

in which case we replace the righthand side of (7) by 0. Then (2) implies that

$$(9) \quad e^{-q_l} \left(1 - M_j^{(\nu)}\right) y_m^{(\nu)} \in \mathcal{A}^{\leq -k_{j+1}} \left(I^{(\nu-1)} \cap I^{(\nu)}\right) \text{ if } m = l \text{ or } m \prec l \text{ on } I^{(\nu)}.$$

Define $w_l^{(\nu)} = y_l^{(\nu)}$, $\forall \nu \in \mathbf{Z}$ with $\theta_{\nu+1} \geq b_1$ and and from these by downward recursion in ν with $a_1 < \theta_{\nu-1} < \theta_\nu < b_1$:

$$(10) \quad w_l^{(\nu-1)} = M_j^{(\nu)} w_l^{(\nu)} \text{ if } j := \max\{t : [\theta_{\nu-1}, \theta_\nu] \subset I_t\}.$$

We will show that there exist constants $c_m(\nu)$ such that if $\theta_\nu > a_1$:

$$(11) \quad w_l^{(\nu)} - y_l^{(\nu)} = \sum_{m \in J(\nu)} c_m(\nu) y_m^{(\nu)}$$

if

$$(12) \quad J(\nu) := \{m \in \{1, \dots, n\} : m \neq l, \kappa_{ml} = k_p, \theta_\nu \in I_p, m \prec l \text{ on } (a_p, \theta_{\nu+1})\}.$$

If $m \in J(\nu)$ then $a_p \leq \theta_{\nu-1}$ and $m \prec l$ on $I^{(\nu)}$. Hence (4) follows from (11). Since $w_l^{(\nu)} - w_l^{(\nu-1)} = \left(1 - M_j^{(\nu)}\right) w_l^{(\nu)}$ we obtain (5) from (11), (12) and (9).

Proof of (11). If $\theta_{\nu+1} \geq b_1$ then $w_l^{(\nu)} = y_l^{(\nu)}$ and (11) follows. Next suppose (11) holds for some ν with $[\theta_{\nu-1}, \theta_\nu] \subset I_1$. From (10) and (7) it follows that

$$(13) \quad w_l^{(\nu-1)} - y_l^{(\nu-1)} = \sum_{\theta_{\lambda l} = \theta_\nu, \kappa_{\lambda l} \leq k_j} \alpha_\lambda(l, \nu) y_\lambda^{(\nu-1)} + \sum_{m \in J(\nu)} c_m(\nu) M_j^{(\nu)} y_m^{(\nu)},$$

where

$$(14) \quad j := \max\{t : [\theta_{\nu-1}, \theta_\nu] \subset I_t\},$$

$$(15) \quad \kappa_{\lambda l} = k_s, s \leq j, \kappa_{ml} = k_p, \theta_\nu \in I_p, m \prec l \text{ on } (a_p, \theta_{\nu+1}).$$

We only have to show that the righthand side of (13) is a linear combination of $y_h^{(\nu-1)}$ with $h \in J(\nu-1)$. As $[\theta_{\nu-1}, \theta_\nu] \subset I_j \subset I_s$ and $\{\theta_\nu - \pi/k_s, \theta_\nu\}$ is a $(\lambda \prec l)$ -Stokes pair which by assumption is not included in I_s we have $\theta_\nu - \pi/k_s \leq a_s$ and therefore $\lambda \prec l$ on (a_s, θ_ν) and $\lambda \in J(\nu-1)$.

Remains to consider the terms $M_j^{(\nu)} y_m^{(\nu)}$ in (13), so with $m \in J(\nu)$. If $j < p$ then since $\theta_\nu \in I_p$, we have $\theta_{\nu-1} \notin I_p$ (cf. (14)). Therefore $\theta_{\nu-1} = a_p$, $m \prec l$ on $I^{(\nu)}$ (cf. (15)) and $M_j^{(\nu)} y_m^{(\nu)} = 0$ (cf. (8)). Finally suppose $p \leq j$. Then $\theta_{\nu-1} \in I_j \subset I_p$ and $m \in J(\nu-1)$. We have to show that for h in the sum in (7), so if $\theta_{hm} = \theta_\nu$, $\kappa_{hm} = k_i$, $i \leq j$, we have $h \in J(\nu-1)$. Now $h \prec m$ on $(\theta_\nu - \pi/k_i, \theta_\nu)$. From this and (15) we get $h \prec m \prec l$ on (a, θ_ν) , where $a := \max\{\theta_\nu - \pi/k_i, a_p\} < \theta_\nu$. Since $q_{hl} = q_{hm} + q_{ml}$ we have $\kappa_{hl} = k_\mu$ where $\mu = \max\{i, p\}$. Then $\mu \leq j$, $a_p \leq a_\mu \leq a_j < \theta_\nu < b_j \leq b_\mu$. Hence the

condition on Stokes pairs implies $a_\mu \geq \theta_\nu - \pi/k_\mu \geq \theta_\nu - \pi/k_i$ and so $a_\mu \geq a$. Therefore $h \prec l$ on (a_μ, θ_ν) , i.e. $h \in J(\nu - 1)$. Thus (11) holds in general.

The uniqueness statement follows from the next Proposition 1.5. \square

Proposition 1.5. *Let $j \in \{1, \dots, r\}$, $k := k_j$, $m := k_{j+1}$. Let I be an open interval of length $> \frac{\pi}{k}$. Suppose there exist a finite covering $\{I^{(\nu)}\}_{\nu=1}^N$ of I and solutions $u_l^{(\nu)}$ and $v_l^{(\nu)}$ of (D) , $\nu = 1, \dots, N$, $l = 1, \dots, n$, satisfying the following conditions*

- 1) $u_l^{(\nu)}(z) \sim \hat{y}_l(z)$ on $I^{(\nu)}$,
- 2) $e^{-q_l} \left(u_l^{(\nu)} - u_l^{(\nu-1)} \right) \in \mathcal{A}^{\leq -m} (I^{(\nu)} \cap I^{(\nu-1)})$ if $\nu > 1$,
- 3) $v_l^{(\nu)}$ satisfies the same conditions as $u_l^{(\nu)}$ and $e^{-q_l} \left(u_l^{(\nu)} - v_l^{(\nu)} \right) \in \mathcal{A}^{\leq -k} (I^{(\nu)})$.

Then $e^{-q_l} \left(u_l^{(\nu)} - v_l^{(\nu)} \right) \in \mathcal{A}^{\leq -m} (I^{(\nu)})$, $\nu = 1, \dots, N$.

Proof. There exist constants $c_{h,\nu}$ such that

$$(16) \quad v_l^{(\nu)} - u_l^{(\nu)} = \sum_{h \prec l \text{ on } I^{(\nu)}, \kappa_{hl}=k} c_{h,\nu} u_h^{(\nu)} \pmod{e^{q_l} \mathcal{A}^{\leq -m} (I^{(\nu)})}.$$

Hence if $\nu \geq 2$ then on $I^{(\nu)} \cap I^{(\nu-1)}$ we have

$$\begin{aligned} v_l^{(\nu-1)} &= v_l^{(\nu)} \pmod{e^{q_l} \mathcal{A}^{\leq -m} (I^{(\nu)} \cap I^{(\nu-1)})} \\ &= u_l^{(\nu)} + \sum_{h \prec l \text{ on } I^{(\nu)}, \kappa_{hl}=k} c_{h,\nu} u_h^{(\nu)} \pmod{e^{q_l} \mathcal{A}^{\leq -m} (I^{(\nu)} \cap I^{(\nu-1)})}. \end{aligned}$$

In the last sum we have $u_h^{(\nu)} = u_h^{(\nu-1)} \pmod{e^{q_h} \mathcal{A}^{\leq -m} (I^{(\nu)} \cap I^{(\nu-1)})}$, $h \prec l$ on $I^{(\nu)}$ and $\kappa_{hl} = k$. So using (16) with ν replaced by $\nu - 1$ we see that $c_{h,\nu} = c_{h,\nu-1}$ and $c_{h,\nu} \neq 0$ only if $h \prec l$ on $I^{(\nu)} \cup I^{(\nu-1)}$. By varying ν we see that $c_{h,\nu} \neq 0$ only if $h \prec l$ on I which is impossible since $\kappa_{hl} = k$, $|I| > \pi/k$. The assertions now follow from (16) with $c_{h,\nu} = 0$. \square

Remark 1.6. $e^{-q_l} w_{lr}$ is called the **multi-sum of $e^{-q_l} \hat{y}_l$ associated with the multi-interval (I_1, \dots, I_r)** . A generalization of Proposition 1.5 is Watson's lemma (cf. Proposition 2.3). Note that any interval I_j in Theorem 1.4 contains a Stokes direction of level k_j . The construction in the proof of Theorem 1.4 only uses coverings by intervals $I^{(\nu)} = (\theta_{\nu-1}, \theta_{\nu+1})$ and intervals I_j bounded by Stokes directions. It could also be given with upward recursion by choosing $\theta_{\nu_0} > b_1$ in Lemma 1.3. If $y_l^{(\nu)}$ is a normalized solution in the sense of Jurkat (cf. Lemma 1.3) with $\theta_{\nu+1} - \theta_{\nu-1} > \pi/k_r$ then the proof of Theorem 1.4 implies that $e^{-q_l} y_l^{(\nu)}$ is the multisum of $e^{-q_l} \hat{y}_l$ on nested multi-intervals (I_1, \dots, I_r) where $|I_j| > \pi/k_j$, I_j does not contain any $(h \prec l)$ -Stokes pair of level $\kappa_{hl} = k_j$ and either $I_j = (a_j, \theta_{\nu+1})$, $j = 1, \dots, r$, $a_r = \theta_{\nu-1}$ or $I_j = (\theta_{\nu-1}, b_j)$, $j = 1, \dots, r$, $b_r = \theta_{\nu+1}$.

Next we consider the Stokes phenomenon for multi-sums of formal solutions of (D) . As we have seen above it is sufficient to consider multisums on intervals bounded by Stokes directions.

Proposition 1.7. *Let $l \in \{1, \dots, r\}$ and let (I_1, \dots, I_r) and $(\tilde{I}_1, \dots, \tilde{I}_r)$ be nested multi-intervals such that if $j \in \{1, \dots, r\}$ then I_j and \tilde{I}_j have length $> \pi/k_j$ and they do not contain any Stokes pair of level k_j . Moreover, assume that there exist $i \in \{1, \dots, r\}$ with the property $I_j = \tilde{I}_j$ if $j \neq i$, and $I_i \cap \tilde{I}_i = (\theta_\sigma, \theta_\mu)$ such that $\theta_\sigma \in I_i$ and $\{\theta_\sigma, \theta_\mu\}$ is a $(s \prec l)$ -Stokes pair of level $\kappa_{sl} = k_i$ for some $s \in \{1, \dots, r\}$. Let $\Lambda := \{h : \theta_{hl} = \theta_\mu, \kappa_{hl} = k_i\}$ and let u_{lj} and $v_{lj}, j = 1, \dots, r$ satisfy the properties of Theorem 1.4 with respect to (I_1, \dots, I_r) and $(\tilde{I}_1, \dots, \tilde{I}_r)$ respectively.*

Then there exist constants $\gamma_h, h \in \Lambda$ such that

$$(17) \quad v_{lj} - u_{lj} = \sum_{h \in \Lambda} \gamma_h u_{hj} \text{ if } j \geq i.$$

Proof. We may assume that $u_l^{(\nu)}$ and $v_l^{(\nu)}$ are constructed as in the proof of Theorem 1.4. Let $I_i = (\theta_\alpha, \theta_\mu)$ and $\tilde{I}_i = (\theta_\sigma, \theta_\beta)$. Then $\alpha < \sigma < \mu < \beta, (\theta_\alpha, \theta_\beta) \subset I_{i-1}$ and if $i < r$ also $I_{i+1} \subset (\theta_\sigma, \theta_\mu)$ and $\sigma < \mu - 1$. Let $j := \max\{s : \theta_{\nu-1}, \theta_\nu \in I_s\}, \tilde{j} := \max\{s : \theta_{\nu-1}, \theta_\nu \in \tilde{I}_s\}$. If $\nu \geq \beta$ then $j < i, \tilde{j} < i$ and therefore $j = \tilde{j}$. From (10) it now follows that $v_l^{(\nu)} = u_l^{(\nu)}$ if $\nu \geq \beta - 1$.

Let $\nu := \min \left\{ \lambda \geq \mu : v_l^{(\lambda)} = u_l^{(\lambda)} \right\}$. So $\mu \leq \nu \leq \beta - 1, \theta_\nu \in \tilde{I}_i \setminus I_i$. Then $j = i - 1$, and except in case $\nu = \mu = \sigma + 1$ moreover $\tilde{j} = i$. From (10) and (11) it follows that except in case $\nu = \mu = \sigma + 1$:

$$\begin{aligned} v_l^{(\nu-1)} - u_l^{(\nu-1)} &= \left(M_i^{(\nu)} - M_{i-1}^{(\nu)} \right) u_l^{(\nu)} \\ &= \left(M_i^{(\nu)} - M_{i-1}^{(\nu)} \right) \left(y_l^{(\nu)} + \sum_{m \in J_g(\nu)} c_m(\nu) y_m^{(\nu)} \right) \end{aligned}$$

with $g = \max\{t : \theta_\nu, \theta_{\nu+1} \in I_t\}$. Then $g < i$ as $\theta_\nu \notin I_i$. From (7) we get

$$\left(M_i^{(\nu)} - M_{i-1}^{(\nu)} \right) y_m^{(\nu)} = \sum_{\theta_{hm} = \theta_\nu, \kappa_{hm} = k_i} \alpha_h(m, \nu) y_h^{(\nu-1)}.$$

If $m \in J_g(\nu), \kappa_{ml} = k_p, \kappa_{hm} = k_i, \theta_{hm} = \theta_\nu$ then $p \leq g < i$ and $m \prec l$ on $(a_p, \theta_{\nu+1})$. As $q_{hl} = q_{hm} + q_{ml}$ we have $\kappa_{hl} = k_i, \theta_{hl} = \theta_\nu$. Since $\theta_\nu \in \tilde{I}_i$ we have $\theta_\nu - \pi/k_i \notin \tilde{I}_i = (\theta_\mu - \pi/k_i, \theta_\beta)$ and as $\nu \geq \mu$ we get $\nu = \mu$. Hence $v_l^{(\nu)} = u_l^{(\nu)}$ if $\nu \geq \mu$. So if $\mu > \sigma + 1$ we get:

$$(18) \quad v_l^{(\mu-1)} - u_l^{(\mu-1)} = \sum_{h \in \Lambda} \delta_h y_h^{(\mu-1)}.$$

Next we consider (11) for $u_h^{(\mu-1)}$:

$$u_h^{(\mu-1)} = y_h^{(\mu-1)} + \sum_{m \in J_{hi}(\mu-1)} c_{mh}(\mu-1) y_m^{(\mu-1)}$$

where $J_{hi}(\mu-1) := \{m : m \prec h \text{ on } (a_s, \theta_\mu), \kappa_{mh} = k_s, s \leq i\}$. If $h \in \Lambda$, $m \in J_{hi}(\mu-1)$ then $m \in \Lambda$ by the same argument as above. Since the solutions $u_h^{(\mu-1)}$, $h \in \Lambda$, are linearly independent and the same holds for $y_h^{(\mu-1)}$, we obtain

$$(19) \quad v_l^{(\nu)} - u_l^{(\nu)} = \sum_{h \in \Lambda} \gamma_h u_h^{(\nu)} \pmod{e^{q_l} \mathcal{A}^{\leq -k_{j+1}}(I^{(\nu)})}$$

for $\nu = \mu - 1, j = i$. From the construction of $u_l^{(\nu)}$ and $v_l^{(\nu)}$ for $\nu < \mu - 1$ by means of (10) we now deduce (19) for $I^{(\nu)} \subset I_j \cap \tilde{I}_j, j \geq i$ if $\mu > \sigma + 1$ and (17) follows.

In case $\nu = \mu = \sigma + 1$ we have $i = r, j = r - 1$ and thus $v_l^{(\mu)} - u_l^{(\mu-1)} = \left(1 - M_{r-1}^{(\mu)}\right) u_l^{(\mu)} = \left(1 - M_{r-1}^{(\mu)}\right) \left(y_l^{(\mu)} + \sum_{m \in J_{r-1}(\mu)} c_m(\mu) y_m^{(\mu)}\right)$. From this and (7) we deduce in the same way as above $v_l^{(\mu)} - u_l^{(\mu-1)} = \sum_{h \in \Lambda} \gamma_h u_h^{(\mu-1)}$ which implies (17) since $v_{lr} = u_{lr}^{(\mu)}$ and $u_{lr} = u_{lr}^{(\mu-1)}$. \square

Remark 1.8. Proposition 1.7 shows that the only contributions to the Stokes phenomenon come from solutions which have as exponential factor $\exp q_h$ such that $\{\theta_\sigma, \theta_\mu\}$ is a $(h \prec l)$ -Stokes pair of level $\kappa_{hl} = k_i$. So $\exp q_{hl}$ has maximal descent near 0 of order k_i in the direction $\theta_\mu - \pi/(2k_i)$, a so-called singular or anti-Stokes direction of level k_i (cf. [5], [17]). For calculations of the Stokes multipliers see [5], [6] and Example 5.10.

The Stokes phenomenon of level k_i occurs in general if in Proposition 1.7 the condition on $I_i \cap \tilde{I}_i$ is replaced by: $I_i \cup \tilde{I}_i$ contains exactly one Stokes pair $\{\theta_\sigma, \theta_\mu\}$ of level k_i and this is a $(s \prec l)$ -Stokes pair for some $s, \theta_\sigma \in I_i$. Without affecting the multisums we may replace I_i by $(\theta_\alpha, \theta_\mu)$ and \tilde{I}_i by $(\theta_\sigma, \theta_\beta)$ with suitable α, β such that $\alpha < \sigma, \mu < \beta$, in view of Proposition 1.5. Now again Proposition 1.7 is applicable. The case where there are more than one i with $I_i \neq \tilde{I}_i$ can be reduced to the case with a single such i .

2. Some basic properties of quasi-functions and multisums.

In this section we introduce some notations that will be used throughout the paper. Unfortunately, there is no uniformity of notation in the existing literature on Gevrey series and functions and the like. Furthermore, we recall a number of known properties of quasi-functions and multi-sums and prove some new results of a rather technical nature (cf. [1], [21], [20], [24]).

Definition 2.1. By $\mathcal{A}^{(0)}$ we denote the sheaf on \mathbf{R} of holomorphic functions admitting an asymptotic expansion $\in \mathbf{C}[[z]]$ as $z \rightarrow 0$ in some sector with

vertex at O and by $\mathcal{A}^{(k)}$ the subsheaf of functions that are Gevrey of order $\frac{1}{k}$. If $f \in \mathcal{A}^{(0)}$ its asymptotic expansion will be denoted by \hat{f} or $J(f)$. By $\mathcal{A}^{<0}$ we denote the kernel of the map $J : \mathcal{A}^{(0)} \rightarrow \mathbf{C}[[z]]$.

By $\mathbf{C}[[z]]_k$ we denote the set of formal power series that are Gevrey of order k^{-1} .

Let $k > 0$ and let I be an interval of \mathbf{R} , open, half-open or closed. A k -precise quasi-function f on I is a section on I of the quotient-sheaf $\mathcal{Q}_k := \mathcal{A}/\mathcal{A}^{\leq -k}$, i.e. $f \in \mathcal{Q}_k(I) = \mathcal{A}/\mathcal{A}^{\leq -k}(I)$. A k -precise quasi-function f can be represented by a collection of functions $\{f_j\}_{j \in \mathcal{J}}$ defined and analytic on an open covering $\{I_j\}_{j \in \mathcal{J}}$ of I . Two such collections $\{f_j\}_{j \in \mathcal{J}}$ defined on a covering $\{I_j\}_{j \in \mathcal{J}}$ and $\{f'_j\}_{j \in \mathcal{J}'}$ defined on a covering $\{I'_j\}_{j \in \mathcal{J}'}$ are considered equivalent if $f_j|_{I_j \cap I'_h} - f'_h|_{I_j \cap I'_h} \in \mathcal{A}^{\leq -k}(I_j \cap I'_h)$ for all $j \in \mathcal{J}$ and $h \in \mathcal{J}'$ such that $I_j \cap I'_h \neq \emptyset$. We say that f is bounded, has exponential growth of order $l > 0$, etc. if the functions $f_j, j \in \mathcal{J}$ have this property. If, for all $j \in \mathcal{J}$, $f_j \in \mathcal{A}^{(k)}(I_j)$ then the asymptotic expansion of f_j is independent of j . This asymptotic expansion will again be denoted by \hat{f} or $J(f)$.

k -precise quasi-functions with at most subexponential growth of order k , i.e. sections of the sheaf $\mathcal{Q}_k^{< k} := \mathcal{A}^{< k}/\mathcal{A}^{\leq -k}$, have a property of analytic continuation. The following proposition is due to Malgrange [19, “quasi-analyticité relative”]. It can be derived from Proposition 2.4 below.

Proposition 2.2. *Let $k > 0$, I an interval of \mathbf{R} and $f \in \mathcal{Q}_k^{< k}(I)$. If the germ of f vanishes in a point θ of I then $f=0$. More generally, the result also holds if we replace the condition that f vanishes in θ by: On a neighborhood I_0 of θ f is represented by a function which has exponential decrease of order k in the direction θ .*

Proposition 2.3. *Let $f \in \mathcal{A}^{\leq -k}/\mathcal{A}^{< -k}(I)$ where $k > 0$ and I is an interval with length $> \pi/k$. Then $f = 0$.*

This proposition extends a result for ordinary functions (i.e. $f \in \mathcal{A}^{\leq -k}(I)$), due to Watson. In the present form it can be found in Malgrange-Ramis [21] (lemme de Watson relatif) and Kostov [15] (cf. also Il’yashenko [11]). We give another proof using the following proposition:

Proposition 2.4. *Let f be holomorphic and of exponential type in the neighborhood of ∞ in a sector S with vertex 0. Let the extended indicator function $H_f : S \rightarrow [-\infty, \infty)$ be defined by $H_f(z) := \limsup_{r \rightarrow \infty} r^{-1} \log |f(rz)|$ if $z \in S$. Then H_f is homogeneous of order 1 and convex on S . In particular: If the segment $[z_1, z_2] \subset S$ and $H_f(z_j) < A_j$ where $A_j \in \mathbf{R}$, $j = 1, 2$, then*

$$f(r(\lambda z_1 + (1 - \lambda)z_2)) = O(1) \exp\{r(\lambda A_1 + (1 - \lambda)A_2)\}$$

as $r \rightarrow \infty$, uniformly in $\lambda \in [0, 1]$.

This result can be deduced from the Phragmén-Lindelöf theorem as has been shown by E.G.F. Thomas (private communication). It also follows from the subharmonicity and homogeneity of H_f (cf. [10, p. 313]). The restriction of H_f to the unit circle is the usual indicator function.

Next consider the case that $f \in \mathcal{A}^{\leq 1}/\mathcal{A}^{< -1}(I)$ where I is an interval (a, b) . Then we may define the extended indicator function for f as follows. Let $I_j = (a_j, b_j)$, $j = 1, 2$ be intervals with nonempty intersection and such that f may be represented by functions $f_j \in \mathcal{A}^{\leq 1}(I_j)$ on I_j . Let $g_j(z) = f_j(z^{-1})$ on a neighborhood of ∞ in the sector $S_j : -b_j < \arg z < -a_j$. Then the extended indicator function H_{g_j} is convex on S_j and moreover $H_{g_1} = H_{g_2}$ on $S_1 \cap S_2$ since $g_1 - g_2 \in \mathcal{A}^{< -1}(S_1 \cap S_2)$ (cf. [15]). Thus we obtain a uniquely defined function on the sector $S : -b < \arg z < -a$ which is convex on overlapping subsectors of S and hence is convex on S . Moreover it is homogeneous of order 1. We denote this function by \tilde{H}_f .

Proof of Proposition 2.3. We may assume $k = 1$ without loss of generality. Then \tilde{H}_f is defined on a sector S of opening $> \pi$ and \tilde{H}_f is negative and convex on S . From this it follows that \tilde{H}_f has to be a negative constant on lines which belong entirely to S . Since any pair of points in S can be connected by segments on such lines it follows that \tilde{H}_f is a negative constant in S . Because \tilde{H}_f is homogeneous of degree 1 this has to be $-\infty$. So by proposition 2.4 each of the representatives of f has supra-exponential decrease of order 1 and therefore $f = 0$. \square

Proof of Proposition 2.2. We may assume that $k = 1$. Suppose that f is represented by a function f_0 on I_0 . Let S_0 be the sector with $z \in S_0$ iff $\arg z \in I_0$. Then \tilde{H}_{f_0} is negative in the direction $-\theta$ and since it is nonpositive on S_0 (by the assumption) and convex it has to be negative on S_0 . Hence $f|_{I_0} \in \mathcal{A}^{\leq -1}(I_0)$. Repeating this reasoning we obtain a chain of subintervals of I on which the representatives of f are sections of $\mathcal{A}^{\leq -1}$. So $f = 0$. \square

Lemma 2.5 (“Borel-Ritt”, cf. [21]). *The mapping $J : \mathcal{A}^{(0)}/\mathcal{A}^{< 0} \rightarrow \mathbf{C}[[z]]$ is an isomorphism of sheaves of differential algebras and so is its “restriction” $J : \mathcal{A}^{(k)}/\mathcal{A}^{\leq -k} \rightarrow \mathbf{C}[[z]]_k$.*

Definition 2.6. Let $r \in \mathbf{N}$, $r > 1$, let $0 < k_1 < \dots < k_r$ and $\mathbf{k} = (k_1, \dots, k_r)$. For $j = 1, \dots, r$, let I_j be an open, half-open or closed interval of \mathbf{R} . If $I_r \subset \dots \subset I_1$ we call $\mathbf{I} := (I_1, \dots, I_r)$ a nested multi-interval. Let f_j be a k_j -precise quasifunction on I_j : $f_j \in \mathcal{Q}_{k_j}(I_j)$, $j \in \{1, \dots, r\}$. If, for all $j \in \{2, \dots, r\}$,

$$f_j \pmod{\mathcal{A}^{\leq -k_{j-1}}} = f_{j-1}|_{I_j}$$

we call $\mathbf{f} := (f_1, \dots, f_r)$ a \mathbf{k} -precise (or (k_1, \dots, k_r) -precise) quasifunction on the nested multi-interval \mathbf{I} . The set of all \mathbf{k} -precise quasifunctions on

\mathbf{I} will be denoted by $\mathcal{Q}_{(k_1, \dots, k_r)}(I_1, \dots, I_r)$ or $\mathcal{Q}_{\mathbf{k}}(\mathbf{I})$. By $\mathcal{Q}_{\mathbf{k}}^{\leq l}(\mathbf{I})$, $\mathcal{Q}_{\mathbf{k}}^{\leq -l}(\mathbf{I})$, $\mathcal{Q}_{\mathbf{k}}^{(l)}(\mathbf{I})$, etc. we denote the sets of \mathbf{k} -precise quasifunctions on \mathbf{I} that have subexponential growth of order l , exponential decrease of order l , that are Gevrey of order $1/l$, etc.

Definition 2.7. Let $r \in \mathbf{N}$, let $0 < k_1 < \dots < k_{r+1} = \infty$. Let $\hat{f} \in \mathbf{C}[[z]]_{k_1}$ and $f_0 = J^{-1}(\hat{f})$. For $j = 1, \dots, r$ let I_j be an open interval of \mathbf{R} of length $> \frac{\pi}{k_j}$, or a half-open or closed interval of length $\geq \frac{\pi}{k_j}$, such that $I_r \subset \dots \subset I_1$. If there exists $\mathbf{f} = (f_1, \dots, f_r) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{(k_1)}(I_1, \dots, I_r)$ such that $f_1 \pmod{\mathcal{A}^{\leq -k_1}} = f_0|_{I_1}$, the formal power series \hat{f} is (k_1, \dots, k_r) -summable on (I_1, \dots, I_r) with (k_1, \dots, k_r) -sum (or multi-sum) (f_1, \dots, f_r) . The set of all (k_1, \dots, k_r) -sums on (I_1, \dots, I_r) will be denoted by $\Sigma_{\mathbf{k}}(\mathbf{I})$, where $\mathbf{k} = (k_1, \dots, k_r)$ and $\mathbf{I} = (I_1, \dots, I_r)$.

A formal series \hat{f} of the form

$$\hat{f}(z) = \sum_{\alpha \in \mathcal{J}} \sum_{l=0}^p \hat{f}^{\alpha l}(z) z^{\alpha} (\log z)^l$$

where $p \in \mathbf{N}$, \mathcal{J} is a finite subset of \mathbf{C} and $\hat{f}^{\alpha l} \in \mathbf{C}[[z]]$ for all l and α , will be called \mathbf{k} -summable on the multi-interval \mathbf{I} , with \mathbf{k} -sum (f_1, \dots, f_r) , if $\hat{f}^{\alpha l}$ is \mathbf{k} -summable on the multi-interval \mathbf{I} for each $\alpha \in \mathcal{J}$ and each $l \in \{1, \dots, p\}$, with \mathbf{k} -sum $(f_1^{\alpha l}, \dots, f_r^{\alpha l})$, such that

$$f_j(z) = \sum_{\alpha \in \mathcal{J}} \sum_{l=0}^p f_j^{\alpha l}(z) z^{\alpha} (\log z)^l, \quad j = 1, \dots, r.$$

Let $d_j \in \mathbf{R}$, $j = 1, \dots, r$. $\mathbf{d} := (d_1, \dots, d_r)$ is called an admissible multi-direction with respect to \mathbf{k} if, for $j = 2, \dots, r$,

$$|d_j - d_{j-1}| \leq \frac{\pi}{2k_{j-1}} - \frac{\pi}{2k_j}.$$

\hat{f} is \mathbf{k} -summable in the multi-direction \mathbf{d} if \hat{f} is \mathbf{k} -summable on the multi-interval (I_1, \dots, I_r) , where $I_j = [d_j - \frac{\pi}{2k_j}, d_j + \frac{\pi}{2k_j}]$. By $\mathbf{C}\{z\}_{\mathbf{k}, \mathbf{d}}$ we denote the set of all formal power series that are \mathbf{k} -summable in the multi-direction \mathbf{d} .

An admissible multi-direction $\mathbf{d} \in \mathbf{R}^r$ is called a **singular direction** of \hat{f} if $\hat{f} \notin \mathbf{C}\{z\}_{\mathbf{k}, \mathbf{d}}$.

Let $\hat{f} \in \mathbf{C}[[z]]_{k_1}$ and $f_0 = J^{-1}(\hat{f})$ and suppose there exist $s \in \mathbf{N}$ and, if $s > 1$, positive numbers $k_1 < \dots < k_s$, an admissible multi-direction (d_1, \dots, d_s) with respect to (k_1, \dots, k_s) and $(f_1, \dots, f_{s-1}) \in \mathcal{Q}_{(k_2, \dots, k_s)}(I_1, \dots, I_{s-1})$, where $I_j = [d_j - \frac{\pi}{2k_j}, d_j + \frac{\pi}{2k_j}]$, $j = 1, \dots, s-1$, such that $f_1 \pmod{\mathcal{A}^{\leq -k_1}} = f_0|_{I_1}$. d_s is called a **singular direction of level k_s of \hat{f}** if $\hat{f} \notin \mathbf{C}\{z\}_{\mathbf{k}', \mathbf{d}'}$

for any $\mathbf{k}' = (k'_1, \dots, k'_r)$ with $r \geq s$ and any admissible multi-direction $\mathbf{d}' = (d'_1, \dots, d'_r)$ such that $k'_j = k_j$ and $d'_j = d_j$ for $j = 1, \dots, s$.

Let $\hat{f} \in \mathbf{C}[[z]]$, $k > 0$ and $\theta \in \mathbf{R}$. The pair $\{\theta, \theta + \frac{\pi}{k}\}$ will be called a **Stokes pair of level k** for \hat{f} if the number $\theta + \frac{\pi}{2k}$ is a singular direction of level k for \hat{f} . By $\mathbf{C}\{z\}_{\mathbf{k}}$ we denote the set of all $f \in \mathbf{C}[[z]]$ with the property that $\hat{f} \in \mathbf{C}\{z\}_{\mathbf{k}, \mathbf{d}}$ for every admissible multi-direction $\mathbf{d} = (d_1, \dots, d_r) \in \mathbf{R}^r$, except for a finite number of values of each single direction d_1, \dots, d_r .

If \hat{f} is (k_1, \dots, k_r) -summable with (k_1, \dots, k_r) -sum $\mathbf{f} = (f_1, \dots, f_r)$, we say that $\hat{f} \pmod{\mathbf{C}\{z\}}$ is (k_1, \dots, k_r) -summable with (k_1, \dots, k_r) -sum $\mathbf{f} \pmod{\mathbf{C}\{z\}}$.

The above definition of \mathbf{k} -summability is easily seen to be equivalent to the following.

Definition 2.8. Let $\mathbf{k} := (k_1, \dots, k_r)$ with $0 < k_1 < \dots < k_r$ and $\mathbf{I} := (I_1, \dots, I_r)$ a nested multi-interval and let $I_0 = \mathbf{R}$. The formal power series $\hat{f} \in \mathbf{C}[[z]]_{k_1}$ is \mathbf{k} -summable on \mathbf{I} if $f_0 = J^{-1}(\hat{f})$ has a representative $\{f_{0,\nu}\}$ defined on a covering $\{I_{0,\nu}\}$ of \mathbf{R} , with the property that $f_{0,\nu} - f_{0,\nu+1} \in \mathcal{A}^{\leq -k_{j+1}}(I_{0,\nu} \cap I_{0,\nu+1})$ for all ν such that $I_{0,\nu} \cup I_{0,\nu+1} \subset I_j$.

Remark 2.9. Obviously, if (f_1, \dots, f_r) is a (k_1, \dots, k_r) -sum on (I_1, \dots, I_r) , then $f_j \in \mathcal{Q}_{k_{j+1}}^{(k_1)}(I_j)$ for all $j \in \{1, \dots, r\}$. Suppose that $(f'_1, \dots, f'_{r-1}, f_r)$ is another (k_1, \dots, k_r) -sum on (I_1, \dots, I_r) . Then we have, for all $j \in \{0, \dots, r\}$,

$$f_j|_{I_r} = f'_j|_{I_r} = f_r \pmod{\mathcal{A}^{\leq -k_{j+1}}}.$$

By Proposition 2.2, this implies that $f_j = f'_j$ for all $j \in \{0, \dots, r\}$. Thus the quasi-functions f_0, \dots, f_{r-1} are uniquely determined by f_r . **Therefore, we will sometimes simply denote the multi-sum (f_1, \dots, f_r) by f_r .** More generally, suppose that $\mathbf{I} = (I_1, \dots, I_r)$ is a nested multi-interval, $\mathbf{k} = (k_1, \dots, k_r)$ with $0 < k_1 < \dots < k_r$ and $(f_1, \dots, f_r) \in \mathcal{Q}_{\mathbf{k}}^{\leq k_1}(\mathbf{I})$. Then the quasifunctions f_1, \dots, f_r are uniquely determined by f_r .

Let $0 < k_1 < \dots < k_r$. Suppose we are given a formal power series \hat{f} and, for every $j \in \{1, \dots, r\}$, an interval $(\alpha_j, \beta_j) \subset \mathbf{R}$. The following statements are equivalent: (i) (α_j, β_j) contains no singular direction of level k_j for \hat{f} , and (ii) $(\alpha_j - \frac{\pi}{2k_j}, \beta_j + \frac{\pi}{2k_j})$ contains no Stokes pair of level k_j for \hat{f} . This can be deduced from Lemma 2.11 below. The next lemma is an immediate consequence of this fact.

Lemma 2.10. *Let $r \in \mathbf{N}$, $0 < k_1 < \dots < k_{r+1} = \infty$ and let (I_1, \dots, I_r) be a nested multi-interval with the property that $|I_j| > \frac{\pi}{k_j}$ for $j = 1, \dots, r$. A formal power series \hat{f} is (k_1, \dots, k_r) -summable on (I_1, \dots, I_r) if and only if, for $j = 1, \dots, r$, I_j does not contain any Stokes pair of level k_j for \hat{f} .*

Lemma 2.11. *Let $r \in \mathbf{N}$, let $0 < k_1 < \dots < k_{r+1} = \infty$. Let I_j , $j = 0, \dots, r$, be open intervals of \mathbf{R} with the property that $I_r \subset I_{r-1} \subset \dots \subset I_0$. For $j = 0, \dots, r$, let $\{I_j^i\}_{i \in \mathcal{J}}$ be an open covering of I_j such that $I_r^i \subset I_{r-1}^i \subset \dots \subset I_0^i$ for all $i \in \mathcal{J}$, where \mathcal{J} is an index set. Moreover, assume that $I_1^{i_1} \cap I_1^{i_2} \neq \emptyset$ for some $i_1, i_2 \in \mathcal{J}$ implies $I_r^{i_1} \cap I_r^{i_2} \neq \emptyset$. Suppose there exist $f^i = (f_0^i, \dots, f_r^i) \in \mathcal{Q}_{(k_1, \dots, k_{r+1})}^{< k_1}(I_0^i, \dots, I_r^i)$, $i \in \mathcal{J}$, with the property that*

$$f_r^{i_1}|_{I_r^{i_1} \cap I_r^{i_2}} = f_r^{i_2}|_{I_r^{i_1} \cap I_r^{i_2}}$$

for all $i_1, i_2 \in \mathcal{J}$ such that $I_r^{i_1} \cap I_r^{i_2} \neq \emptyset$. Then there exists a unique $f = (f_0, \dots, f_r) \in \mathcal{Q}_{(k_1, \dots, k_{r+1})}^{< k_1}(I_0, \dots, I_r)$, such that, for all $j \in \{0, \dots, r\}$,

$$f_j|_{I_j^i} = f_j^i, \quad i \in \mathcal{J}.$$

Proof. By means of induction on $r - j$ we shall prove the existence and uniqueness of $f_j \in \mathcal{Q}_{k_{j+1}}^{< k_1}(I_j)$ such that $f_j|_{I_j^i} = f_j^i$ for all $i \in \mathcal{J}$. For $j = r$ this statement is true. Now suppose it is true for some $j \leq r$. Then we have

$$f_{j-1}^i|_{I_j^i} = f_j|_{I_j^i} \pmod{\mathcal{A}^{\leq -k_j}}, \quad i \in \mathcal{J}.$$

Hence it follows that

$$(f_{j-1}^{i_2} - f_{j-1}^{i_1})|_{I_j^{i_1} \cap I_j^{i_2}} = 0 \pmod{\mathcal{A}^{\leq -k_j}}$$

for all $i_1, i_2 \in \mathcal{J}$ such that $I_r^{i_1} \cap I_r^{i_2} \neq \emptyset$. In view of Proposition 2.2 this implies that

$$(f_{j-1}^{i_2} - f_{j-1}^{i_1})|_{I_{j-1}^{i_1} \cap I_{j-1}^{i_2}} = 0 \pmod{\mathcal{A}^{\leq -k_j}}.$$

Consequently, there exists a unique $f_{j-1} \in \mathcal{Q}_{k_j}^{< k_1}(I_{j-1})$ such that $f_{j-1}|_{I_{j-1}^i} = f_{j-1}^i|_{I_{j-1}^i}$ for $i \in \mathcal{J}$. Thus the statement is true for all $j \in \{0, \dots, r\}$. This implies that, for all $j \in \{1, \dots, r\}$, and $i \in \mathcal{J}$,

$$f_{j-1}|_{I_j^i} = f_j|_{I_j^i} \pmod{\mathcal{A}^{\leq -k_j}}$$

and thus

$$f_{j-1}|_{I_j} = f_j \pmod{\mathcal{A}^{\leq -k_j}}.$$

Hence the result follows. \square

Lemma 2.12. *Let $\mathbf{k} := (k_1, \dots, k_r)$ and let \mathbf{d}^1 and $\mathbf{d}^2 \in \mathbf{R}^r$ be two multi-directions with the property that $|d_j^1 - d_j^2| < \frac{\pi}{k_j}$ for all $j \in \{1, \dots, r\}$. Let \hat{f} be \mathbf{k} -summable in the multi-directions \mathbf{d}^1 and \mathbf{d}^2 with multi-sums (f_1^1, \dots, f_r^1) and (f_1^2, \dots, f_r^2) , respectively. If $f_r^1 = f_r^2$, then \hat{f} is \mathbf{k} -summable in every multi-direction \mathbf{d} such that $d_j \in [\min\{d_j^1, d_j^2\}, \max\{d_j^1, d_j^2\}]$.*

Proof. Let $k_{r+1} = \infty$. By assumption, there exists a positive number ϵ such that, for $i \in \{1, 2\}$, $(f_0, f_1^i, \dots, f_r^i) \in \mathcal{Q}_{(k_1, \dots, k_{r+1})}^{(k_1)}(I_0^i, \dots, I_r^i)$, where $I_0^1 = I_0^2 = \mathbf{R}$ and $I_j^i = \left(d_j^i - \epsilon - \frac{\pi}{2k_j}, d_j^i + \epsilon + \frac{\pi}{2k_j}\right)$ for $j \in \{1, \dots, r\}$. Let $f_0 = J^{-1}(\hat{f})$, $I_0 = \mathbf{R}$ and, for $j = 1, \dots, r$, let $I_j = \left(\min\{d_j^1, d_j^2\} - \frac{\pi}{2k_j} - \epsilon, \max\{d_j^1, d_j^2\} + \frac{\pi}{2k_j} + \epsilon\right)$. Obviously, $I_j^1 \cap I_j^2 \neq \emptyset$ for all $j \in \{1, \dots, r\}$. Thus, according to Lemma 2.11, there exist quasi-functions f_1, \dots, f_r such that $(f_0, f_1, \dots, f_r) \in \mathcal{Q}_{(k_1, \dots, k_{r+1})}^{<k_1}(I_0, \dots, I_r)$. \square

Lemma 2.13. *Let $r \in \mathbf{N}$, let $0 < k_1 < \dots < k_{r+1} = \infty$. Let I_j^i , $j = 1, \dots, r$, $i \in \mathbf{Z}$, be open intervals of \mathbf{R} such that $I_r^i \subset I_{r-1}^i \subset \dots \subset I_1^i$ and $|I_j^i \cap I_j^{i+1}| > \frac{\pi}{k_j}$ for all $i \in \mathbf{Z}$. Suppose there exist $f^i = (f_1^i, \dots, f_r^i) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{<k_1}(I_1^i, \dots, I_r^i)$, $i \in \mathbf{Z}$, with the property that*

$$\left(f_1^i|_{I_1^i \cap I_1^{i+1}} - f_1^{i+1}|_{I_1^i \cap I_1^{i+1}}\right) \pmod{\mathcal{A}^{\leq -k_1}} = 0$$

for all $i \in \mathbf{Z}$. Let $I_j := \cup_{i \in \mathbf{Z}} I_j^i$. Then there exists a unique $f = (f_1, \dots, f_r) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{<k_1}(I_1, \dots, I_r)$, such that, for all $j \in \{1, \dots, r\}$,

$$f_j|_{I_j^i} = f_j^i, \quad i \in \mathbf{Z}.$$

Proof. By means of induction on j one shows that, for all $j \in \{1, \dots, r\}$ and all $i \in \mathbf{Z}$,

$$f_j^i - f_j^{i+1} \in \mathcal{Q}_{k_{j+1}}^{\leq -k_j}(I_j^i \cap I_j^{i+1})$$

and, consequently, by Proposition 2.3,

$$f_j^i|_{I_j^i \cap I_j^{i+1}} - f_j^{i+1}|_{I_j^i \cap I_j^{i+1}} = 0.$$

Hence the quasifunctions f_j^i can be glued together to an element of $\mathcal{Q}_{k_{j+1}}^{<k_1}(\cup_{i \in \mathbf{Z}} I_j^i)$ and the statement of the lemma follows immediately. \square

The following lemma is concerned with the Stokes phenomenon, i.e. the difference between two multi-sums of the same formal power series on different, overlapping, multi-intervals. It will be used in §4 and §5.

Lemma 2.14. *Let $r \in \mathbf{N}$, $0 < k_1 < k_2 < \dots < k_{r+1} = \infty$. Let $i \in \{1, \dots, r\}$ and let $\mathbf{I}, \mathbf{I}' \in \mathbf{R}^r$ be two nested multi-intervals with the property that $I_j = I'_j$ and $|I_j| > \frac{\pi}{k_j}$ for all $j \neq i$ and $|I_i \cap I'_i| = \frac{\pi}{k_i}$. Suppose that there exist $\mathbf{f} = (f_1, \dots, f_r) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{<k_1}(\mathbf{I})$ and $\mathbf{f}' = (f'_1, \dots, f'_r) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{<k_1}(\mathbf{I}')$, such that $(f'_1 - f_1) \pmod{\mathcal{A}^{\leq -k_1}} = 0$. Then $f'_j = f_j$ for all*

$j < i$, whereas

$$f'_i - f_i \in \mathcal{Q}_{k_{i+1}}^{\leq -k_i} \left(\left(-\frac{\pi}{2k_i}, \frac{\pi}{2k_i} \right) \right)$$

and, for all $j > i$,

$$f'_j - f_j \in \mathcal{Q}_{k_{j+1}}^{\leq -k_i}(I_j).$$

Proof. For all $j \in \{1, \dots, r\}$ we have

$$f'_j - f_j \in \mathcal{Q}_{k_{j+1}}^{\leq k_1}(I_j \cap I'_j)$$

and, for all $j > 1$,

$$(f'_j - f_j) \pmod{\mathcal{A}^{\leq -k_j}} = (f'_{j-1} - f_{j-1})|_{I_j \cap I'_j}.$$

By means of induction on j and Proposition 2.3 it is shown that, for all $j \leq i$,

$$f'_j - f_j \in \mathcal{Q}_{k_{j+1}}^{\leq -k_j}(I_j \cap I'_j)$$

and $f'_j = f_j$ for all $j < i$, and $f'_i - f_i \in \mathcal{Q}_{k_{i+1}}^{\leq -k_i}(I_i \cap I'_i)$. The remaining part of the lemma now follows easily. \square

In various applications (e.g. in the theory of linear differential equations, cf. §1) one deals with multi-summable formal power series having a finite number of singular directions of each level in any finite interval. In that case, each quasi-function in a multi-sum of the formal series possesses a finite representative, consisting of multi-sums of the same formal power series.

Lemma 2.15. *Let $r \in \mathbf{N}$, $0 < k_1 < k_2 < \dots < k_{r+1} = \infty$. Let $\hat{f} \in \mathbf{C}[[z]]_{k_1}$ and suppose that \hat{f} possesses a (k_1, \dots, k_r) -sum (f_1, \dots, f_r) on the multi-interval (I_1, \dots, I_r) where I_1, \dots, I_r are open. Assume that the interval I_1 only contains a finite number of Stokes pairs of level k_j for each $j \in \{2, \dots, r\}$. Then the quasi-function f_j has a finite representative of the form $\{f^{(\nu)} : \nu \in \{M_j, \dots, N_j\}\}$, where $M_1 \leq M_2 \leq \dots \leq M_r \leq N_r \leq \dots \leq N_2 \leq N_1$ and $f^{(\nu)}$ is a (k_1, \dots, k_r) -sum of \hat{f} for each $\nu \in \{M_1, \dots, N_1\}$.*

Proof. There exists a covering of I_1 by intervals $I^{(\nu)} = (a^{(\nu)}, b^{(\nu)})$, $\nu = M_1, \dots, N_1$, where M_1 and N_1 are integers with $M_1 < N_1$, such that $|I^{(\nu)}| > \pi/k_r$, $I^{(\nu)}$ does not contain any Stokes pair of level k_j for $j = 2, \dots, r$, $a^{(\nu)} < a^{(\nu+1)} < b^{(\nu)} < b^{(\nu+1)}$, and for all $j \in \{1, \dots, r\}$ there exist integers M_j and N_j such that $I_j = (a^{(M_j)}, b^{(N_j)})$. Hence $M_1 \leq M_2 \leq \dots \leq M_r \leq N_r \leq \dots \leq N_2 \leq N_1$. We may assume that $M_r = N_r$.

Let $\nu \in \{M_1, \dots, N_1\}$ and let j be the largest integer such that $I^{(\nu)} \subset I_j$. Then we define $I_h^{(\nu)} := I_h$ if $h \in \{1, \dots, j\}$ and $I_r^{(\nu)} := I^{(\nu)}$. If $j < r - 1$, there exist open intervals $I_h^{(\nu)}$ of length $> \pi/k_h$, $h \in \{j+1, \dots, r-1\}$, such

that $I_h^{(\nu)}$ does not contain any Stokes pair of level k_h and $(I_1^{(\nu)}, \dots, I_r^{(\nu)})$ is a nested multi-interval. Then, by Corollary 2.10, \hat{f} is multi-summable on this multi-interval with multisum $(f_1^{(\nu)}, \dots, f_r^{(\nu)})$. Note that $I_1^\nu = I_1$ and $f_1^\nu = f_1$. Let $f^{(\nu)} := f_r^{(\nu)}$.

If $M_j \leq \nu \leq N_j$ and $h \in \{1, \dots, j\}$, then $I_h^{(\nu)} = I_h$ and from Proposition 2.3 it then follows that $f_h^{(\nu)} = f_h$. Furthermore, $f_j|_{I^{(\nu)}} = f_j^{(\nu)}|_{I^{(\nu)}} = f^{(\nu)} \pmod{\mathcal{A}^{\leq -k_{j+1}}}$ which implies that f_j can be represented by $\{f^{(\nu)}, \nu = M_j, \dots, N_j\}$. \square

3. Multisummability and Cauchy-Heine transforms.

Suppose we are given two open intervals I_1 and I_2 such that $I_1 \cap I_2 \neq \emptyset$, and two analytic functions $f_1 \in \mathcal{A}^{(0)}(I_1)$ and $f_2 \in \mathcal{A}^{(0)}(I_2)$, admitting the same asymptotic expansion \hat{f} as $z \rightarrow 0$. Obviously, the difference $f_1 - f_2$ belongs to $\mathcal{A}^{<0}(I_1 \cap I_2)$. Conversely, if we are given an interval $I = (\alpha, \beta)$ and a function $f \in \mathcal{A}^{<0}(I)$, we can construct two functions $f_1 \in \mathcal{A}^{(0)}((\alpha, \beta + 2\pi))$ and $f_2 \in \mathcal{A}^{(0)}((\alpha - 2\pi, \beta))$ with the property that $\hat{f}_1 = \hat{f}_2$ and $f_1 - f_2 = f$. To this end, choose $\rho \in \mathbf{C}$ such that $\arg \rho \in I$ and f is holomorphic on $(0, \rho)$. Now define f_1 and f_2 by

$$f_1(z) := CH_\rho^-(f) := \int_0^\rho \frac{f(\zeta)}{2\pi i(\zeta - z)} d\zeta \quad -2\pi < \arg z - \arg \rho < 0$$

and

$$f_2(z) := CH_\rho^+(f) := \int_0^\rho \frac{f(\zeta)}{2\pi i(\zeta - z)} d\zeta \quad 0 < \arg z - \arg \rho < 2\pi.$$

$CH_\rho^-(f)$ and $CH_\rho^+(f)$ are so-called Cauchy-Heine transforms of f . Note that $CH_\rho^-(f)(z) = CH_\rho^+(f)(ze^{2\pi i})$. By deformation of the path of integration, the functions f_1 and f_2 can be continued analytically to elements of $\mathcal{A}((\alpha - 2\pi, \beta))$ and $\mathcal{A}((\alpha, \beta + 2\pi))$, respectively. With the aid of the expansion $\sum_{n=0}^\infty \zeta^{-n-1} z^n$ for $(\zeta - z)^{-1}$, it can be shown that f_1 and f_2 admit an asymptotic expansion $\widehat{CH}_\rho(f) = \sum_{n=0}^\infty a_n z^n$ as $z \rightarrow 0$, where

$$a_n = \frac{1}{2\pi i} \int_0^\rho f(\zeta) \zeta^{-n-1} d\zeta.$$

It is easily seen that $f_1 - f_2 = f$. A different choice of ρ leads to a pair of functions \tilde{f}_1 and \tilde{f}_2 such that $\tilde{f}_1 - \tilde{f}_1 = \tilde{f}_2 - f_2$ and this difference is regular at O . The construction described above is extremely useful in many applications. For example, suppose we are given a formal power series $\hat{f} \in \mathbf{C}[[z]]$. \hat{f} defines an element $f_0 \in \mathcal{A}^{(0)}/\mathcal{A}^{<0}(S^1)$, where S^1 is the unit circle and, with a slight abuse of notation, we let $\mathcal{A}^{(0)}$ and $\mathcal{A}^{<0}$ denote sheaves on S^1 instead of \mathbf{R} . f_0 can be represented by a 0-cochain of $\mathcal{A}^{(0)}$ with respect to some open covering

$\{U_i\}_{i=1}^N$ of S^1 and its coboundary defines an element of $H^1(S^1, \mathcal{A}^{<0})$, which is independent of the choice of representative of f_0 . Conversely, if $\{g_i\}_{i=1}^M$ represents an element Φ of $H^1(S^1, \mathcal{A}^{<0})$, then, with the aid of Cauchy-Heine transforms of the g_i , we can construct a 0-cochain $\{f_i\}_{i=1}^N$ with coboundary $\{g_i\}_{i=1}^M$ and asymptotic expansion $\hat{f}_i = \hat{f} \in \mathbf{C}[[z]]$ for all $i \in \{1, \dots, N\}$. The equivalence class modulo $\mathbf{C}\{z\}$ of the formal power series \hat{f} is independent of the choice of cochain representing Φ . This construction yields a well-known isomorphism from $H^1(S^1, \mathcal{A}^{<0})$ onto $\mathbf{C}[[z]]/\mathbf{C}\{z\}$. In an analogous manner one can construct an isomorphism from $H^1(S^1, \mathcal{A}^{\leq -k})$ onto $\mathbf{C}[[z]]_k/\mathbf{C}\{z\}$, for any positive number k (cf. [18, 23]). In this section we derive similar results for multi-summable power series. To that end, we begin by studying Cauchy-Heine transforms of functions with properties that are characteristic of differences of multi-sums.

In this and the next section, we shall frequently use the symbols \pm and \mp to combine two statements: One statement is obtained by reading the upper signs, the other one by reading the lower signs.

Definition 3.1. Let $f \in \mathcal{A}^{<0}(I)$ where I is an open interval of \mathbf{R} . By $CH^\pm(f)$ we denote the equivalence class modulo $\mathbf{C}\{z\}$ of the function defined by the (analytic continuation of the) Cauchy-Heine transform

$$CH_\rho^\pm(f) := \int_0^\rho \frac{f(\zeta)}{2\pi i(\zeta - z)} d\zeta \quad 0 < \pm(\arg z - \arg \rho) < 2\pi$$

where $|\rho|$ is sufficiently small and $\arg \rho \in I$.

By $\widehat{CH}(f)$ we denote the equivalence class modulo $\mathbf{C}\{z\}$ of the formal power series expansion of the function defined above.

Lemma 3.2 (cf. Ramis, [23]). *Let $k > 0$ and let $a, b \in \mathbf{R} : a < b$. If $f \in \mathcal{A}^{\leq -k}((a, b))$ then*

$$CH^+(f) \in \mathcal{A}^{(k)}((a, b + 2\pi))/\mathbf{C}\{z\}$$

and

$$CH^-(f) \in \mathcal{A}^{(k)}((a - 2\pi, b))/\mathbf{C}\{z\}.$$

For a proof of this lemma cf. [19, pp. 114, 115].

Corollary 3.3. *Let $k > 0$, let a, b be real numbers such that $a < b$, and $f \in \mathcal{A}^{\leq -k}((a, b))$. Then $F := \widehat{CH}(f) \in \mathbf{C}\{z\}_{\mathbf{k}, \mathbf{d}}/\mathbf{C}\{z\}$ for all $d \in (a - 2\pi + \frac{\pi}{2k}, b - \frac{\pi}{2k}) \bmod 2\pi$. $CH^+(f)$ is the k -sum of F in the directions $d \in (a + \frac{\pi}{2k}, b + 2\pi - \frac{\pi}{2k})$ and $CH^-(f)$ is the k -sum of F in the directions $d \in (a - 2\pi + \frac{\pi}{2k}, b - \frac{\pi}{2k})$. In particular, if $a = -\frac{\pi}{2k}$ and $a < b + 2\pi - \frac{\pi}{k}$, then $CH^+(f)$ is a k -sum in the directions $d \in (0, \epsilon)$ for some $\epsilon > 0$, and if $a < -\frac{\pi}{2k}$ then it is a k -sum in the direction 0. Similarly, if $b = \frac{\pi}{2k}$ and $a < b + 2\pi - \frac{\pi}{k}$, then $CH^-(f)$ is a k -sum in the directions $d \in (-\epsilon, 0)$ for some $\epsilon > 0$, and if $b > \frac{\pi}{2k}$ it is a k -sum in the direction 0.*

Lemma 3.4. *Let $I_0 = (a_0, b_0) \subset I = (a, b)$, $0 < k < l$, $f_0 \in \mathcal{A}^{\leq -k}(I_0)$, $f \in \mathcal{A}^{\leq -k}/\mathcal{A}^{\leq -l}(I)$, such that $f|_{I_0} = f_0 \pmod{\mathcal{A}^{\leq -l}}$. Then there exists $F \in \mathcal{A}^{(k)}/\mathcal{A}^{\leq -l}(a, b + 2\pi)$ with the property that*

$$(20) \quad F|_{(a_0, b_0 + 2\pi)} \pmod{\mathbf{C}\{z\}} = CH^+(f_0) \pmod{\mathcal{A}^{\leq -l}}.$$

If there exist $b^+ \in (a, b)$, $b^+ < b_0 + 2\pi$ and $f^+ \in \mathcal{A}^{\leq -k}(b^+, b)$ such that $f|_{(b^+, b)} = f^+ \pmod{\mathcal{A}^{\leq -l}}$ then there exists $g^+ \in \mathcal{A}^{(l)}(b^+, b_0 + 2\pi)$ with the property that

$$(21) \quad CH^+(f_0)|_{(b^+, b_0 + 2\pi)} = CH^+(f^+)|_{(b^+, b_0 + 2\pi)} + g^+ \pmod{\mathbf{C}\{z\}}.$$

Similarly, if there exist $a^- \in (a, b)$, $a^- > a_0 - 2\pi$ and $f^- \in \mathcal{A}^{\leq -k}(a, a^-)$ such that $f|_{(a, a^-)} = f^- \pmod{\mathcal{A}^{\leq -l}}$ then there exists $g^- \in \mathcal{A}^{(l)}(a_0, a^- + 2\pi)$ with the property that

$$(22) \quad CH^+(f_0)|_{(a_0, a^- + 2\pi)} = CH^+(f^-)|_{(a_0, a^- + 2\pi)} + g^- \pmod{\mathbf{C}\{z\}}.$$

Proof. Let f be represented by $\{f_j\}_{j \in \mathcal{J}}$ on a covering $\{I_j\}_{j \in \mathcal{J}}$ of I where \mathcal{J} is an interval of \mathbf{Z} containing 0, and $I_j = (a_j, b_j)$ with $a_j < a_{j+1} < b_j < b_{j+1}$. Thus $f_j \in \mathcal{A}^{\leq -k}(I_j)$, $f_j - f_{j+1} \in \mathcal{A}^{\leq -l}(I_j \cap I_{j+1})$.

According to Lemma 3.2, $CH^+(f_j)$ possesses a representative $\phi_j \in \mathcal{A}^{(k)}(a_j, b_j + 2\pi)$. Let $\psi_j := \phi_j - \phi_{j+1}$. Then, again by Lemma 3.2, $\psi_j \in \mathcal{A}^{(l)}(a_{j+1}, b_j + 2\pi)$ with an asymptotic expansion $\hat{\psi}_j \in \mathbf{C}[[z]]_l$.

Let $N \geq 0$, $N \in \mathcal{J}$ and define $\rho_N := \sum_{j=0}^{N-1} J^{-1} \hat{\psi}_j$ (cf. Lemma 2.5). Thus $\rho_N \in \mathcal{A}^{(l)}/\mathcal{A}^{\leq -l}(\mathbf{R})$. If $a_N < b_0 + 2\pi$ we define $\chi_N = \sum_{j=0}^{N-1} \psi_j$, so that

$$(23) \quad \chi_N \in \mathcal{A}^{(l)}(a_N, b_0 + 2\pi) \text{ and } \phi_0|_{(a_N, b_0 + 2\pi)} = \phi_N|_{(a_N, b_0 + 2\pi)} + \chi_N$$

and

$$\rho_N|_{(a_N, b_0 + 2\pi)} = \chi_N \pmod{\mathcal{A}^{\leq -l}}.$$

Define

$$F_N = (\phi_N + \rho_N)|_{(a_N, b_N + 2\pi)} \pmod{\mathcal{A}^{\leq -l}}.$$

Then $F_N \in \mathcal{A}^{(k)}/\mathcal{A}^{\leq -l}(a_N, b_N + 2\pi)$ and if $a_N < b_0 + 2\pi$ then $F_N|_{(a_N, b_0 + 2\pi)} = \phi_0|_{(a_N, b_0 + 2\pi)} \pmod{\mathcal{A}^{\leq -l}}$.

Assume that also $N + 1 \in \mathcal{J}$. Let ρ_N be represented by $\tilde{\rho}_N \in \mathcal{A}^{(l)}(\tilde{I})$ on some interval $\tilde{I} \subset (a_{N+1}, b_N + 2\pi)$. Then F_N may be represented on \tilde{I} by $\phi_N + \tilde{\rho}_N = \phi_{N+1} + \tilde{\rho}_{N+1}$ where $\tilde{\rho}_{N+1} := \psi_N + \tilde{\rho}_N$, and so $\tilde{\rho}_{N+1}$ is a representative of $\hat{\rho}_{N+1}$ on \tilde{I} . Hence F_N and F_{N+1} have a representative in common and so by quasi-analyticity $F_N|_{(a_{N+1}, b_N + 2\pi)} = F_{N+1}|_{(a_{N+1}, b_N + 2\pi)}$. The sheaf property now implies that the functions F_N with $N \geq 0$ determine an element $F \in \mathcal{A}^{(k)}/(\mathcal{A}^{\leq -l}(a_0, b + 2\pi))$ such that (20) holds.

In a similar way we may extend ϕ_0 to quasi-functions on intervals which start to the left of a_0 by choosing $N \leq 0, N \in \mathcal{J}$ and

$$\chi_N = - \sum_{j=N}^{-1} \psi_j \text{ if } a_0 < b_N + 2\pi \text{ and } \rho_N := \sum_{j=N}^{-1} \hat{\psi}_j.$$

The corresponding F_N with $N < 0$ can be pasted with those with $N \geq 0$ to obtain $F \in \mathcal{A}^{(k)}/\mathcal{A}^{\leq -l}(a, b + 2\pi)$.

If the condition on f^+ is fulfilled then we may choose N such that $a_N = b^+, b_N = b, f_N = f^+, \phi_N$ is a representative of $CH^+(f^+)$ and thus we obtain (21) from (23) with $g^+ := \chi_N$. Similarly if the condition on f^- is fulfilled. \square

From this lemma we will derive:

Corollary 3.5. *Let $r \in \mathbf{N}, 0 < k_1 < \dots < k_r < k_{r+1} = \infty, \mathbf{I} := (I_1, \dots, I_r)$ be a nested multi-interval with $I_j = (a_j, b_j), j = 1, \dots, r$ and $\mathbf{f} := (f_1, \dots, f_r) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{\leq -k_1}(\mathbf{I})$. Let $\tilde{I}_j := (a_j, b_j + 2\pi)$ and $\tilde{\mathbf{I}} := (\tilde{I}_1, \dots, \tilde{I}_r)$.*

Then there exists $\mathbf{F} = (F_1, \dots, F_r) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{(k_1)}(\tilde{\mathbf{I}})$ such that $F_r \pmod{\mathbf{C}\{z\}} = CH^+(f_r)$. If $|\tilde{I}_j| > \pi/k_j$ for $j = 1, \dots, r$ - so in particular if $k_1 \geq 1/2$ - then \mathbf{F} is the (k_1, \dots, k_r) -sum of \hat{F}_0 on $\tilde{\mathbf{I}}$ where $\hat{F}_0 \pmod{\mathbf{C}\{z\}} = \widehat{CH}(f_r)$.

If, in addition, for all $j \in \{1, \dots, r-1\}$ there exist $b_j^+ \in (a_j, b_j)$ and $f_j^+ \in \mathcal{A}^{\leq -k_1}(b_j^+, b_j)$ such that $b_j^+ < b_r + 2\pi$ and f_j is represented by f_j^+ on (b_j^+, b_j) then for $j = 1, \dots, r$ there exists $g_j^+ \in \mathcal{A}^{(k_j)}(b_{j-1}^+, b_j + 2\pi)$ with $b_0^+ := b_1^+$ such that

$$(24) \quad CH^+(f_r) = \sum_{j=1}^r g_j^+ \pmod{\mathbf{C}\{z\}}$$

where in both sides we take the restriction to the intersection of the intervals on which the terms are well-defined.

Similarly, if for all $j \in \{1, \dots, r-1\}$ there exists $a_j^- \in (a_j, b_j)$ such that $a_r < a_j^- + 2\pi$ and f_j is represented by a function on (a_j, a_j^-) then for $j = 1, \dots, r$ there exists $g_j^- \in \mathcal{A}^{(k_j)}(a_j, a_{j-1}^- + 2\pi]$ with $a_0^- := a_1^-$ such that

$$(25) \quad CH^+(f_r) = \sum_{j=1}^r g_j^- \pmod{\mathbf{C}\{z\}}$$

where in both sides we take the restriction to the intersection of the intervals on which the terms are well-defined.

Proof. We may apply the previous lemma with $I_0 := I_r, f_0 := f_r, k := k_1, f := f_j, l := k_{j+1}, I := I_j$. Hence there exist $F_j \in \mathcal{A}^{(k_1)}/\mathcal{A}^{\leq -k_{j+1}}(\tilde{I}_j)$

such that

$$F_j|_{\tilde{I}_r} = \phi_r \pmod{\mathcal{A}^{\leq -k_{j+1}}},$$

where ϕ_r is a representative of $CH^+(f_r)$. Hence $F_{j-1}|_{\tilde{I}_r} = F_j \pmod{\mathcal{A}^{\leq -k_j}}|_{\tilde{I}_r}$. With the aid of Proposition 2.2 we now deduce the first assertion.

Next let the assumptions concerning (24) be satisfied. Let $f_j|_{(b_j^+, b_j)}$ be represented by $f_j^+ \in \mathcal{A}^{\leq -k_1}(b_j^+, b_j)$, $j = 1, \dots, r-1$. Let $f_r^+ := f_r, b_r^+ := a_r$. Then we may apply the preceding lemma with $k := k_1, l := k_j, f_0 := f_j^+, I_0 := (b_j^+, b_j), f := f_{j-1}, I := I_{j-1}, f^+ := f_{j-1}^+, b^+ := b_{j-1}^+$ where $j = 2, \dots, r$. It follows that there exists $g_j^+ \in \mathcal{A}^{(k_j)}(b_{j-1}^+, b_j + 2\pi)$ such that

$$\begin{aligned} CH^+(f_j)^+|_{(b_{j-1}^+, b_j + 2\pi)} \\ = g_j^+ + CH^+(f_{j-1}^+)|_{(b_{j-1}^+, b_j + 2\pi)} \pmod{\mathbf{C}\{z\}}, j = 2, \dots, r. \end{aligned}$$

With $g_1^+ := CH^+(f_1^+) \in \mathcal{A}^{(k_1)}(b_1^+, b_1 + 2\pi)$ (cf. Lemma 3.2) we obtain (24) by addition. The proof of (25) is similar. \square

Remark 3.6. Similar results hold for CH^- since $CH^-(f)(z) = CH^+(f)(ze^{2\pi i})$. The corollary may be applied to the case that $\mathbf{f} = h\mathbf{g}$ where $\mathbf{g} \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{\leq k_1}(\mathbf{I})$ and $h \in \mathcal{A}^{\leq -k_1}(I_1)$.

The above corollary is a generalization of Balser: [1, §6.7, Proposition 4].

According to a well-known result, due to B. Malgrange and Y. Sibuya (cf. [23]), the set $\mathbf{C}[[z]]_k/\mathbf{C}\{z\}$ is isomorphic to $H^1(S^1, \mathcal{A}^{\leq -k})$, where S^1 denotes the unit circle. In the next two theorems we consider the restriction of this isomorphism to the set of multi-summable power series and give a characterization of its image in $H^1(S^1, \mathcal{A}^{\leq -k})$.

Theorem 3.7. *Let $r \in \mathbf{N}$, $0 < k_1 < \dots < k_{r+1} = \infty$. Suppose we are given admissible multi-intervals $\mathbf{I}^i = (I_1^i, \dots, I_r^i)$, where $I_j^i = (\alpha_j^i, \beta_j^i)$, $j \in \{1, \dots, r\}$, $i \in \{1, \dots, N+1\}$, with the following properties*

- $|I_j^i| > \frac{\pi}{k_j}$,
- $\{I_r^i\}_{i=1}^N$ is a covering of $[0, 2\pi)$,
- $\alpha_j^i < \beta_j^{i+1} < \alpha_j^{i+1} < \beta_j^i < \beta_j^{N+1}$ for all $i \in \{1, \dots, N\}$ and $j \in \{1, \dots, r\}$,
- $|I_1^{i+1} \cap I_1^i| < 2\pi$ for all $i \in \{1, \dots, N\}$.

Let $I_j^{N+1} = I_j^1 + 2\pi$. Suppose there exist $\mathbf{g}^i \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{\leq -k_1}(\mathbf{I}^{i+1} \cap \mathbf{I}^i)$, $i \in \{1, \dots, N\}$. Then there exists a unique $\hat{F} \in \mathbf{C}[[z]]_{k_1}$, (k_1, \dots, k_r) -summable on \mathbf{I}^i with sum \mathbf{f}^i for all $i \in \{1, \dots, N+1\}$, such that $f_r^{N+1}(z) = f_r^1(ze^{-2\pi i})$ and $f_r^{i+1} - f_r^i = g_r^i$ for all $i \in \{1, \dots, N\}$. Moreover, $\hat{F} \pmod{\mathbf{C}\{z\}} = \sum_{i=1}^N \widehat{CH}(g_r^i)$.

Proof. For $i \in \{1, \dots, N+1\}$, let $f_r^i = \sum_{h=1}^N CH^{d_{ih}}(g_r^h)$, where $d_{ih} = +$ if $h < i$ and $d_{ih} = -$ if $h \geq i$. From Corollary 3.5 we deduce that f_r^i is a (k_1, \dots, k_r) -sum on (I_1^i, \dots, I_r^i) . Moreover, $f_r^{i+1} - f_r^i = CH^+(g_r^i) - CH^-(g_r^i) = g_r^i$ and

$$f_r^{N+1}(z) = \sum_{h=1}^N CH^+(g_r^h)(z) = \sum_{h=1}^N CH^-(g_r^h)(ze^{-2\pi i}) = f_r^1(ze^{-2\pi i}).$$

□

Theorem 3.8. *Let $\frac{1}{2} < k_1 < \dots < k_r$, $k_{r+1} = \infty$ and $\hat{f} \in \mathbf{C}[[z]]$. $\hat{f} \in \mathbf{C}\{z\}_{(k_1, \dots, k_r)}$ if and only if there exist $d_i \in [0, 2\pi)$, $f_r^i \in \mathcal{A}\left(\left(d_i - \frac{\pi}{2k_r}, d_{i+1} + \frac{\pi}{2k_r}\right)\right)$, $i = 1, \dots, N$, where $d_{N+1} := d_1 + 2\pi$, and $g_j^i \in \mathcal{Q}_{k_{j+1}}^{\leq -k_1}\left(\left(d_{i+1} - \frac{\pi}{2k_j}, d_{i+1} + \frac{\pi}{2k_j}\right)\right)$, $j = 1, \dots, r$, $i = 1, \dots, N$, with the following properties:*

$$\begin{aligned} f_r^i(z) &\sim \hat{f}(z) \text{ as } z \rightarrow 0, \arg z \in (d_i - \frac{\pi}{2k_r}, d_{i+1} + \frac{\pi}{2k_r}), i = 1, \dots, N, \\ g_j^i \pmod{\mathcal{A}^{\leq -k_j}} &= g_{j-1}^i \Big|_{\left(d_{i+1} - \frac{\pi}{2k_{j-1}}, d_{i+1} + \frac{\pi}{2k_{j-1}}\right)}, j = 2, \dots, r, i = 1, \dots, N, \\ f_r^{i+1} - f_r^i &= g_r^i, \text{ for all } i \in \{1, \dots, N\}, \text{ where } f_r^{N+1} \text{ is defined by} \\ f_r^{N+1}(z) &= f_r^1(ze^{-2\pi i}). \end{aligned}$$

4. The Stokes phenomenon in the direction 0.

In the two remaining sections we shall restrict ourselves to the study of (k_1, \dots, k_r) -sums on multi-intervals (I_1, \dots, I_r) , where $I_j = [-\frac{\pi}{2k_j}, \frac{\pi}{2k_j})$, or $I_j = (-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}]$, or $I_j = [-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}]$. Therefore, we introduce the following conventions. If $r \in \mathbf{N}$ and $0 < k_1 < \dots < k_r$ are given, we write

$$I_j^0 = \left[-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right], \quad I_j^+ = \left(-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right] \\ \text{and } I_j^- = \left[-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right), \quad j \in \{1, \dots, r\}.$$

We say that (f_1, \dots, f_r) is a (k_1, \dots, k_r) -sum in the multi-direction $(d_1, \dots, d_r) \in \{+, 0, -\}^r$ if (f_1, \dots, f_r) is a (k_1, \dots, k_r) -sum on (I_1, \dots, I_r) , where $I_j = I_j^{d_j}$.

Definition 4.1. By Σ^\pm we denote the differential algebra of all multi-sums in the direction \pm , i.e. the set of $f \in \mathcal{A}_0$ (\mathcal{A}_0 denotes the stalk in O of the sheaf \mathcal{A}) with the following property: There exist a positive integer r , positive numbers k_1, \dots, k_r such that $k_1 < \dots < k_r < k_{r+1} = \infty$ and $(f_1, \dots, f_r) \in \Sigma_{(k_1, \dots, k_r)}^\pm(I_1^\pm, \dots, I_r^\pm)$ such that $f_r = f$.

By Σ^0 we denote the differential algebra of all multi-sums in the direction 0.

By $\Sigma^{<0}$ we denote the differential algebra of $f \in \mathcal{A}_0$ with the following property: There exist a positive integer r , positive numbers k_1, \dots, k_r such that $k_1 < \dots < k_r < k_{r+1} = \infty$ and $(f_1, \dots, f_r) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{\leq -k_1}(I_1, \dots, I_r)$ where $I_j = \left(-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right)$ such that $f_r = f$.

By $\widehat{\Sigma}$ we denote the differential algebra of all formal power series that are multi-summable in the directions $+$ and $-$, and by $\widehat{\Sigma}^0$ the differential algebra of multi-summable power series in the direction 0 . By $\sigma^\pm : \widehat{\Sigma} \rightarrow \Sigma^\pm$ we denote ‘multi-summation in the direction \pm ’, i.e. $\sigma^\pm(\hat{f})$ is the multi-sum of \hat{f} in the multi-direction with components \pm . We will write $\sigma^\pm(\hat{f}) = f^\pm := (f_1^\pm, \dots, f_r^\pm)$, or $\sigma^\pm(\hat{f}) = f_r^\pm$ for short.

Proposition 4.2. $\Sigma^0 = \Sigma^+ \cap \Sigma^-$ and $\widehat{\Sigma}^0$ coincides with the set of all $\hat{f} \in \widehat{\Sigma}$ with the property that $\sigma^+(\hat{f}) = \sigma^-(\hat{f})$. $\sigma := \sigma^+ - \sigma^-$ induces a vector space isomorphism from $\widehat{\Sigma}/\widehat{\Sigma}^0$ onto $\Sigma^{<0}$ with inverse

$$\sigma^{-1}(f) = \widehat{CH}(f) \pmod{\widehat{\Sigma}^0}.$$

Proof. The first two statements follow immediately from Lemma 2.12 (cf. also [22, Lemma 10]). Let $\hat{f} \in \widehat{\Sigma}$. It is easily verified that, for $j = 1, \dots, r$,

$$f_j^+ - f_j^- \in \mathcal{Q}_{k_{j+1}}^{\leq -k_1} \left(-\frac{\pi}{2k_j}, \frac{\pi}{2k_j} \right)$$

and

$$f_j^+ - f_j^- \pmod{\mathcal{A}^{\leq -k_j}} = (f_{j-1}^+ - f_{j-1}^-) \Big|_{\left(-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right)}$$

and thus $\sigma^+(\hat{f}) - \sigma^-(\hat{f}) \in \Sigma^{<0}$. The injectivity of σ is obvious. Now suppose $f \in \Sigma^{<0}$. By Corollary 3.5, $CH^\pm(f)$ is a (k_1, \dots, k_r) -sum in the direction \pm , hence $\widehat{CH}(f) \in \widehat{\Sigma}/\mathbf{C}\{z\}$ and $\sigma(\widehat{CH}(f)) = CH^+(f) - CH^-(f) = f$. \square

The above proposition shows that the Cauchy-Heine transformation is a device by which we can construct, modulo multi-summable power series in the direction 0 , a formal power series with a prescribed Stokes phenomenon in the direction 0 . In what follows we will consider subsets of $\Sigma^{<0}$, i.e. Stokes phenomena of a particular type.

Definition 4.3. Let $r \in \mathbf{N}$. For any $l \in \{0, \dots, r\}$ we define the multi-direction $\theta^{l\pm} \in \{+, -\}^r$ as follows. $\theta_i^{l\pm} = \mp$ for $1 \leq i \leq l$ and $\theta_i^{l\pm} = \pm$ for $l < i \leq r$.

Proposition 4.4. Let $\hat{f} \in \widehat{\Sigma}$. The following conditions are equivalent.

- 1). \hat{f} is (k_1, \dots, k_r) -summable in the multi-direction $\theta^{l\pm}$ for every $l \in \{1, \dots, r\}$.

2). For every $i \in \{1, \dots, r\}$ and every $j \in \{i, \dots, r\}$ there exists a quasi-function F_j^i such that

$$\begin{aligned} F_i^i &\in \mathcal{A}^{\leq -k_i} / \mathcal{A}^{\leq -k_{i+1}} \left(\left(-\frac{\pi}{2k_i}, \frac{\pi}{2k_i} \right) \right), \\ F_j^i &\in \mathcal{A}^{\leq -k_i} / \mathcal{A}^{\leq -k_{j+1}} (I_j^\pm) \text{ if } j > i, \\ (26) \quad F_j^i \pmod{\mathcal{A}^{\leq -k_j}} &= F_{j-1}^i|_{I_j^\pm} \text{ for all } j > i \end{aligned}$$

and

$$(27) \quad \sigma^\mp(\hat{f}) - \sigma^\pm(\hat{f}) = \sum_{i=1}^r F_r^i.$$

The quasi-functions F_j^i ($j \geq i$) are uniquely determined by \hat{f} . Suppose that condition 2) is satisfied and let (f_1^l, \dots, f_r^l) be the (k_1, \dots, k_r) -sum of \hat{f} in the multi-direction θ^{\pm} . Then we have

$$\begin{aligned} f_j^l &= f_j^\pm + \sum_{i=1}^j F_j^i \text{ if } j \leq l, \\ f_j^l &= f_j^\pm + \sum_{i=1}^l F_j^i \text{ if } j > l. \end{aligned}$$

Proof. We prove the statements of the Proposition in the case of the upper signs. Suppose that \hat{f} is (k_1, \dots, k_r) -summable in every multi-direction θ^{l+} , with sum (f_1^l, \dots, f_r^l) . Let $F_j^i := f_j^i - f_j^{i-1}$, $j = i, \dots, r$. We have $f_j^i = f_j^{i-1} \in \mathcal{A}^{(k_1)} / \mathcal{A}^{\leq -k_{j+1}} (I_j^-)$ for all $j < i$, $f_i^i \in \mathcal{A}^{(k_1)} / \mathcal{A}^{\leq -k_{i+1}} (I_i^-)$ and $f_i^{i-1} \in \mathcal{A}^{(k_1)} / \mathcal{A}^{\leq -k_{i+1}} (I_i^+)$. For all $j > i$, both f_j^i and f_j^{i-1} belong to $\mathcal{A}^{(k_1)} / \mathcal{A}^{\leq -k_{j+1}} (I_j^+)$. From Lemma 2.14 we deduce that the quasi-functions F_j^i have the desired properties. In order to prove the uniqueness of F_i^i it suffices to show that $\sum_{i=1}^r F_r^i = 0$ implies $F_j^i = 0$ for all $i \in \{1, \dots, r\}$ and all $j \geq i$. Writing

$$F_r^1 = - \sum_{i=2}^r F_r^i$$

we see that

$$F_r^1|_{(-\frac{\pi}{2k_r}, \frac{\pi}{2k_r})} \in \mathcal{A}^{\leq -k_2} \left(\left(-\frac{\pi}{2k_r}, \frac{\pi}{2k_r} \right) \right).$$

Hence it follows that $F_1^1|_{(-\frac{\pi}{2k_r}, \frac{\pi}{2k_r})} = 0$. By Proposition 2.2 this implies that $F_1^1 = 0$. Using (26) and Proposition 2.3 one easily verifies that $F_j^1 = 0$ for

all $j \geq 1$. By means of induction on i it can now be shown that $F_j^i = 0$ for all $i \in \{1, \dots, r\}$ and all $j \leq i$.

Now suppose that 2) holds. Let $l \in \{1, \dots, r\}$. Let $f_j^l := f_j^+ + \sum_{i=1}^l F_j^i$ if $j \in \{l+1, \dots, r\}$ and $f_j^l := f_j^-$ for $j \in \{1, \dots, l\}$. Obviously, $f_j^l \in \mathcal{A}^{(k_1)}/\mathcal{A}^{\leq -k_{j+1}}(I_j^+)$ for $j > l$ and $f_j^l \in \mathcal{A}^{(k_1)}/\mathcal{A}^{\leq -k_{j+1}}(I_j^-)$ for $j \leq l$. Furthermore, it is easily seen that $f_j^l \pmod{\mathcal{A}^{\leq -k_j}} = f_{j-1}^l|_{I_j^+}$ for all $j > l+1$, and $f_j^l \pmod{\mathcal{A}^{\leq -k_j}} = f_{j-1}^l|_{I_j^-}$ for all $j \leq l$. Noting that $f_r^l = f_r^- - \sum_{i=l+1}^r F_r^i$ and $F_i^i \pmod{\mathcal{A}^{\leq -k_i}} = 0$ for all i we find that, for all $j > l$,

$$f_j^l|_{(-\frac{\pi}{2k_r}, \frac{\pi}{2k_r})} = \left(f_j^- - \sum_{i=l+1}^j F_j^i \right) \Big|_{(-\frac{\pi}{2k_r}, \frac{\pi}{2k_r})}.$$

In particular,

$$f_{l+1}^l \pmod{\mathcal{A}^{\leq -k_{l+1}}} \Big|_{(-\frac{\pi}{2k_r}, \frac{\pi}{2k_r})} = f_l^- \Big|_{(-\frac{\pi}{2k_r}, \frac{\pi}{2k_r})}$$

and, by Proposition 2.2, this implies that $f_{l+1}^l \pmod{\mathcal{A}^{\leq -k_{l+1}}} = f_l^-|_{I_{l+1}^+} = f_l^l|_{I_{l+1}^+}$. It remains to be proved that, for $j \leq l$,

$$f_j^- = f_j^+ + \sum_{i=1}^j F_j^i.$$

This follows easily from (26), (27) and the fact that $F_r^i \pmod{\mathcal{A}^{\leq -k_{j+1}}} = 0$ for all $i > j$. \square

Corollary 4.5. *Let $f \in \Sigma^{<0}$. $\widehat{CH}(f)$ is (k_1, \dots, k_r) -summable in the multi-direction θ^l such that $\theta_i^l = \mp$ for $i \leq l$ and $\theta_i^l = \pm$ for $i > l$, for every $l \in \{1, \dots, r\}$, iff f can be written in the form*

$$f = \sum_{i=1}^r F_r^i$$

where the F_r^i are functions with the properties mentioned in Proposition 4.4. Moreover, if these conditions are satisfied, then the multi-sum g_r^l of $\widehat{CH}(f)$ in the multi-direction θ^l is given by

$$g_r^l = CH^\pm(f) + \sum_{i=1}^l F_r^i.$$

Proof. According to Corollary 3.5 and Remark 3.6, $\widehat{CH}(f) \in \hat{\Sigma}$ and $\sigma^\pm(\widehat{CH}(f)) = CH^\pm(f)$. Hence

$$\sigma^\pm(\widehat{CH}(f)) - \sigma^\mp(\widehat{CH}(f)) = \pm f \pmod{\mathbf{C}\{z\}}.$$

The above statements now follow immediately from Proposition 4.4. \square

5. Stokes automorphisms and alien derivations.

A multi-summable formal power series gives rise to a non-trivial Stokes phenomenon if and only if it is divergent. Stokes phenomena can be used in the analytic classification of certain local objects, e.g. locally analytic differential equations. In many cases of interest, a detailed analysis of the Stokes phenomenon associated with such an object will yield a complete set of analytic invariants of this object (i.e. quantities that are invariant under an analytic change of variable).

There is another, essentially equivalent way to obtain these invariants. Suppose, for example, that $\hat{f} = \sum_{n=1}^{\infty} a_n z^n$ is a 1-summable power series. Then its formal Borel transform with respect to the variable z^{-1} : $\sum_{n=1}^{\infty} a_n \frac{t^{n-1}}{\Gamma(n)}$ defines the germ at O of an analytic function. This function can be continued analytically in any direction which is not a singular direction of \hat{f} . Similarly, with a (k_1, \dots, k_r) -summable power series \hat{f} , one can associate r such analytic functions $\varphi_1, \dots, \varphi_r$. φ_1 is the formal Borel transform, with respect to the variable z^{-k_1} , of \hat{f} and the functions $\varphi_2, \dots, \varphi_r$ are so-called accelerates of φ_1 . In many applications, the function φ_j can be continued analytically along paths avoiding a certain discrete set of singular points whose arguments coincide with the singular directions of level k_j of \hat{f} . The singularities of the functions $\varphi_1, \dots, \varphi_r$ determine the type of Stokes phenomenon and, in an appropriate context, the analytic invariants associated with \hat{f} . In order to describe the nature of these singularities, J. Ecalle introduced the so-called alien derivations (cf. [8]). In this section we give an alternative definition derived directly from the Stokes phenomenon. In the sequel we restrict ourselves to the Stokes phenomenon in the direction 0.

Example 5.1. Consider the locally analytic differential equation

$$z^2 \frac{dy}{dz} = f(z, y)$$

where $f \in \mathbf{C}\{z, y\}$ such that $f(0, 0) = 0$ and $\frac{\partial f}{\partial y}(0, 0) = \omega > 0$. It possesses a unique formal solution $\hat{h} \in \mathbf{C}\{z\}_1$ with singular direction 0. There exist formal power series $\hat{h}_n \in \mathbf{C}\{z\}_1$, $n \in \mathbf{N}$, such that

$$\sigma^+(\hat{h}) - \sigma^-(\hat{h}) = \sum_{n=1}^{\infty} e^{-n\omega/z} \sigma^-(\hat{h}_n)$$

where the series in the right-hand side converges if $\operatorname{Re}(1/z)$ is sufficiently small (cf. [7]). σ^+ and σ^- denote the multi-sums defined in the previous section (cf. Definition 4.1).

Example 5.2 (Laplace integrals). Let ϵ_1, ϵ_2 and r be positive numbers, $\epsilon_j < 2\pi, j = 1, 2$ and $U := S(0, \epsilon_1) \cup S(2\pi - \epsilon_2, 2\pi) \cup S((0, 2\pi), r)$ (cf.

Definition 1.1). Let ϕ be an analytic function on U . Then the Laplace transform of ϕ will be defined as follows (cf. [7]). Let C be a contour in U from $\infty \exp(\eta_1 i)$ to $\infty \exp\{(2\pi - \eta_2)i\}$ where $0 < \eta_j < \epsilon_j, j = 1, 2, \eta_1 + \eta_2 < \pi$. Here and in the following we apply a lemma of Ecalle which says that if a function ψ is analytic on a union Γ of finitely many unbounded contours in \mathbf{C} which have asymptotes at ∞ then there exists an entire function E such that $|\psi - E|$ is bounded on Γ (cf. [7]; cf. also a lemma of Sato in [14]). Choosing $\Gamma = C$ and $\psi = \phi$ we see that $\int_C \exp(-t/z) \{\phi(t) - E(t)\} dt$ exists on $S(\eta_1 - \pi/2, \pi/2 - \eta_2)$ and it belongs to $\mathcal{A}^{<1}((\eta_1 - \pi/2, \pi/2 - \eta_2))$. Variation of E gives a modification of this integral by elements of $\mathcal{A}^{<-1}((\eta_1 - \pi/2, \pi/2 - \eta_2))$. Thus we get a section in $\mathcal{A}^{<1}/\mathcal{A}^{<-1}((\eta_1 - \pi/2, \pi/2 - \eta_2))$ which will be denoted by $\mathcal{L}_C \phi$. By variation of η_1, η_2 and C we obtain a quasi-function $\mathcal{L}\phi$ in $\mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2, \pi/2))$ which is called the Laplace integral of ϕ .

Next suppose that there exists $\omega > 0$ such that ϕ possesses analytic continuations ϕ^- and ϕ^+ on $U^- := U \cup (0, \omega) \cup S(-\epsilon_2, 0)$ and $U^+ := U \cup (0, \omega e^{2\pi i}) \cup S(2\pi, 2\pi + \epsilon_1)$ respectively.

Let C^- be a contour in U^- from $\infty \exp(-\eta_2 i)$ to $\infty \exp\{(2\pi - \eta_2)i\}$. Then similarly as above we may define $\mathcal{L}_{C^-} \phi^- \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2 - \eta_2, \pi/2 - \eta_2))$. With C as above we see that $\mathcal{L}_C \phi - \mathcal{L}_{C^-} \phi^-$ has a representative $\int_{C_\omega} \exp(-t/z) \{\phi^-(t) - E^-(t)\} dt$ where $C_\omega = \omega + C$ and E^- is an entire function such that $|\phi^- - E^-|$ is bounded on $C \cup C^- \cup C_\omega$. Hence $\mathcal{L}_C \phi - \mathcal{L}_{C^-} \phi^- = e^{-\omega/z} \mathcal{L}_C(\tau_{-\omega} \phi^-)$ where $\tau_{-\omega}$ is the shift operator over $-\omega$: $(\tau_{-\omega} \psi)(t) := \psi(\omega + t)$. By variation of C^- and η_2 we obtain an extension of $\mathcal{L}_C \phi^-$ to $f^- \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2 - \epsilon_2, \pi/2))$. Moreover, we see that

(28)

$$\mathcal{L}\phi^- f^- = e^{-\omega/z} f_\omega^- \text{ where } f_\omega^- := \mathcal{L}(\tau_{-\omega} \phi^-) \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2, \pi/2)).$$

Similarly we define f^+ starting from $\mathcal{L}_{C^+} \phi^+ \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2 + \eta_1, \pi/2 + \eta_1))$ using a contour C^+ in U^+ from $\infty \exp(\eta_1 i)$ to $\infty \exp\{(2\pi + \eta_1)i\}$. Then $f^+ \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2, \pi/2 + \epsilon_1))$ and (28) holds with the superscripts $-$ replaced by $+$. Moreover, f^- and f^+ determine a quasi-function f in $\mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2 - \epsilon_2, \pi/2 + \epsilon_1))$ such that $\mathcal{L}\phi \pmod{\mathcal{A}^{<-1}} = f^\pm|_{(-\pi/2, \pi/2)} \pmod{\mathcal{A}^{<-1}} = f|_{(-\pi/2, \pi/2)}$.

Thus we have a Stokes phenomenon corresponding to the crossing of the positive axis between 0 and ω :

(29)

$$\left\{ \begin{array}{l} \mathcal{L}\phi = f^\pm + e^{-\omega/z} f_\omega^\pm, f^\pm \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2, \epsilon_1 + \pi/2)), \\ f^- \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\epsilon_2 - \pi/2, \pi/2)), f_\omega^\pm \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2, \pi/2)). \end{array} \right\}$$

So

(30)

$$f^- = f^+ + e^{-\omega/z} f_\omega, \text{ where } f_\omega := f_\omega^+ - f_\omega^- \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2, \pi/2)),$$

and $f_\omega = \mathcal{L}(\tau_{-\omega}(\phi^+ - \phi^-))$. In several applications - for example if ϕ is endlessly analytically continuable (cf. [7]) - it turns out that f_ω has similar properties as f , so that we may repeat the preceding procedure to get better approximations to f^\pm . For example if $\tilde{\omega}$ is the singularity of $\phi^+ - \phi^-$ next to ω on \mathbf{R}_+ then in (30) we have in view of (29)

$$e^{-\omega/z} f_\omega = e^{-\omega/z} F_\omega^+ + e^{-\tilde{\omega}/z} f_\omega^+ \text{ where } F_\omega^+ \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2, \pi/2]),$$

$$f_\omega^+ \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2, \pi/2))$$

and so

$$e^{\tilde{\omega}/z}(f^- - f^+ - e^{-\omega/z} F_\omega^+) \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\pi/2, \pi/2)).$$

These and other, similar, examples have motivated the following definitions.

Definition 5.3. By \mathcal{T}^0 we denote the set of formal series f of the form

$$f = \sum_{\omega \in \mathbf{C}} e^{-\omega/z} f_\omega,$$

where $f_\omega \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}([-\frac{\pi}{2}, \frac{\pi}{2}])$ and $\Omega^0(f) := \{\omega \in \mathbf{C} : f_\omega \neq 0\}$ is a discrete set with the property that $\{|\operatorname{Im} \omega| : \omega \in \Omega^0(f)\}$ and $\{-\operatorname{Re} \omega : \omega \in \Omega^0(f)\}$ are bounded above. $\Omega^0(f)$ will be called the support of f .

It is easily verified that \mathcal{T}^0 is a differential algebra. For all $f, g \in \mathcal{T}^0$ we have $\Omega^0(fg) \subset \Omega^0(f) + \Omega^0(g)$ and

$$(fg)_\omega = \sum_{\omega_1 + \omega_2 = \omega} f_{\omega_1} g_{\omega_2}$$

and

$$\left(\frac{d}{dz}f\right)_\omega = \frac{d}{dz}f_\omega + \omega z^{-2}f_\omega.$$

The unit element is the series f with support $\{0\}$ and $f_0 = 1 \pmod{\mathcal{A}^{<-1}}$. The zero element is the unique element with empty support.

Definition 5.4. By \mathcal{S}^1 we denote the set of quasi-functions $f \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}([-\frac{\pi}{2}, \frac{\pi}{2}])$ with the following property:

There exist a quasi-function $f^- \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}([-\frac{\pi}{2}, \frac{\pi}{2}))$ such that

$$f^- \pmod{\mathcal{A}^{<-1}} = f|_{[-\frac{\pi}{2}, \frac{\pi}{2})},$$

a discrete set $\Omega^1(f)$ of nonnegative numbers, including 0, and, for each $\omega \in \Omega^1(f)$, quasi-functions $F_\omega \in \mathcal{A}^{<1}/\mathcal{A}^{\leq-1}([-\frac{\pi}{2}, \frac{\pi}{2}])$ and $F_\omega^+ \in \mathcal{A}^{<1}/\mathcal{A}^{<-1}((-\frac{\pi}{2}, \frac{\pi}{2}])$, such that $F_0 = f$ and, for all $\omega \in \Omega^1(f)$,

$$F_\omega^+ \pmod{\mathcal{A}^{\leq-1}} = F_\omega|_{(-\frac{\pi}{2}, \frac{\pi}{2}]}$$

and, for each $\omega' \in \Omega^1(f) - \{0\}$,

$$e^{\omega'/z} \left(f^- - \sum_{\omega \in \Omega^1(f): \omega < \omega'} e^{-\omega/z} F_\omega^+ \right) \in \mathcal{A}^{<1}/\mathcal{A}^{<-1} \left(\left(-\frac{\pi}{2}, \frac{\pi}{2} \right) \right).$$

For all $\omega \geq 0$ we define a mapping $S_\omega : \mathcal{S}^1 \rightarrow \mathcal{A}^{<1}/\mathcal{A}^{\leq-1}([-\frac{\pi}{2}, \frac{\pi}{2}])$ by $S_\omega(f) = F_\omega$ if $\omega \in \Omega^1(f)$ and $S_\omega(f) = 0$ otherwise.

By \mathcal{T}^1 we denote the set of series $f \in \mathcal{T}^0$ with the property that $f_\omega \in \mathcal{S}^1$ for all $\omega \in \mathbf{C}$. We define a mapping $\mathfrak{S} : \mathcal{T}^1 \rightarrow \mathcal{T}^0$ by

$$(\mathfrak{S}(f))_\omega = \sum_{\omega_1 + \omega_2 = \omega} S_{\omega_2}(f_{\omega_1}).$$

\mathcal{S}^1 is a differential subalgebra of $\mathcal{A}^{<1}/\mathcal{A}^{\leq-1}([-\frac{\pi}{2}, \frac{\pi}{2}])$ and hence it follows that \mathcal{T}^1 is a differential subalgebra of \mathcal{T}^0 . For all $\omega \geq 0$ and all $f, g \in \mathcal{S}^1$, the following relations hold

$$\begin{aligned} S_\omega(fg) &= \sum_{\omega_1 + \omega_2 = \omega} S_{\omega_1}(f) S_{\omega_2}(g), \\ S_\omega \left(\frac{d}{dz} f \right) &= \frac{d}{dz} S_\omega(f) + \omega z^{-2} S_\omega(f). \end{aligned}$$

Note that S_0 is the identity. (The mapping S_ω is similar to, though not identical with the mapping S_ω^+ defined in [12].) By means of straightforward computations it can be shown that \mathfrak{S} is an injective differential algebra homomorphism. If $f, g \in \mathcal{T}^1$ we have

$$(\mathfrak{S}(fg))_\omega = \sum_{\omega_1 + \omega_2 + \omega'_1 + \omega'_2 = \omega} S_{\omega_2}(f_{\omega_1}) S_{\omega'_2}(g_{\omega'_1}).$$

If $f \in \mathcal{T}^1$ has support $\{\omega\}$, then $\mathfrak{S}(f) = \sum_{\omega' \geq \omega} e^{-\omega'/z} S_{\omega' - \omega}(f_\omega)$. In general,

$$\Omega^0(\mathfrak{S}(f)) = \bigcup_{\omega \in \Omega^0(f)} (\omega + \Omega^1(f_\omega)).$$

Example 5.5. Let $f = f_0$ be the restriction to $[-\frac{\pi}{2}, \frac{\pi}{2}]$ of a global section of $\mathcal{A}^{(1)}/\mathcal{A}^{\leq-1}$ associated with a formal power series $\hat{f}_0 \in \widehat{\Sigma}$ with levels k_1, \dots, k_r , where $k_1 = 1$. Let $\sigma^\pm(\hat{f}_0) = (f_1^\pm, \dots, f_r^\pm)$. Suppose there exists

a discrete set of positive numbers Ω and formal power series $\hat{f}_\omega \in \widehat{\Sigma}$, with multi-sum $\sigma^+(\hat{f}_\omega) = (f_{\omega,1}^+, \dots, f_{\omega,r}^+)$ for each $\omega \in \Omega$, such that

$$f_1^- - f_1^+ = \sum_{\omega \in \Omega} e^{-\omega/z} f_{\omega,1}^+.$$

Then $f \in \mathcal{T}^1$, $\Omega^0(f) = \{0\}$, $\Omega^1(f) = \Omega \cup 0$ and $\mathfrak{S}(f)_\omega = J^{-1}(\hat{f}_\omega)|_{[-\frac{\pi}{2}, \frac{\pi}{2}]}$.

Definition 5.6. For all $n \in \mathbf{N}$ we define:

$$\mathcal{S}^{n+1} = \{f \in \mathcal{S}^1 : S_\omega f \in \mathcal{S}^n \text{ for all } \omega \in \Omega^1(f)\}$$

and

$$\mathcal{T}^{n+1} := \{f \in \mathcal{T}^1 : \mathfrak{S}(f) \in \mathcal{T}^n\}.$$

For all $n \in \mathbf{N}$ and $\omega = (\omega_1, \dots, \omega_n) \in [0, \infty)^n$ we write: $|\omega| = \omega_1 + \dots + \omega_n$ and

$$S_\omega = S_{\omega_n} \dots S_{\omega_1}.$$

For all $f \in \mathcal{S}^n$ we note

$$\Omega^n(f) := \{\omega \in [0, \infty)^n : S_\omega f \neq 0\}.$$

Furthermore, we define

$$\mathcal{S}^\infty = \bigcap_{n=1}^{\infty} \mathcal{S}^n, \quad \mathcal{T}^\infty = \bigcap_{n=1}^{\infty} \mathcal{T}^n,$$

$$\mathcal{S} = \left\{ f \in \mathcal{S}^\infty : \bigcup_{n=1}^{\infty} \{|\omega| : \omega \in \Omega^n(f)\} \text{ is a discrete set} \right\}$$

and

$$\mathcal{T} = \left\{ f \in \mathcal{T}^\infty : \bigcup_{\omega_0 \in \Omega^0(f)} \bigcup_{n=1}^{\infty} \{\omega_0 + |\omega| : \omega \in \Omega^n(f_{\omega_0})\} \text{ is discrete} \right\}.$$

By means of induction on n , one easily proves the following lemma.

Lemma 5.7. *Let $n \in \mathbf{N}$. $f \in \mathcal{T}^n$ if and only if $f_\omega \in \mathcal{S}^n$ for all $\omega \in \Omega^0(f)$. Similarly, $f \in \mathcal{T}$ if and only if $f_\omega \in \mathcal{S}$ for all $\omega \in \Omega^0(f)$.*

Note that, for a given ω ,

$$((\mathfrak{S} - id)^n f)_\omega = \sum_{\omega_1, \dots, \omega_n > 0} S_{\omega_n} \dots S_{\omega_1} (f_{\omega - (\omega_1 + \dots + \omega_n)})$$

and this sum equals 0 for all but a finite number of integers n . Therefore, the infinite sum $\sum_{n=0}^{\infty} (-1)^n (\mathfrak{S} - id)^n f$, so $\mathfrak{S}^{-1} f$ is well-defined for all $f \in \mathcal{T}$ and its support is discrete. (Alternatively, we could define \mathcal{T} to be the largest

subalgebra of \mathcal{T}^1 that is invariant under \mathfrak{S} .) Thus \mathfrak{S} is a differential algebra automorphism of \mathcal{T} . We define the ‘directional alien derivation’ Δ by

$$\Delta := \log \mathfrak{S} = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} (\mathfrak{S} - id)^n.$$

Δ is a derivation of \mathcal{T} (cf. [7]). We have

$$(\Delta f)_{\omega} = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sum_{\omega' \in \mathbf{C}} \sum_{\omega'' \in (0, \infty)^n: |\omega''| + \omega' = \omega} S_{\omega''}(f_{\omega'}).$$

Δ can be decomposed as follows: $\Delta = \sum_{\omega > 0} \dot{\Delta}_{\omega}$, where $\dot{\Delta}_{\omega}$ is defined by

$$(31) \quad (\dot{\Delta}_{\omega} f)_{\omega'} = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sum_{\omega'' \in (0, \infty)^n: |\omega''| = \omega} S_{\omega''}(f_{\omega' - \omega}).$$

$\dot{\Delta}_{\omega}$ is a derivation of \mathcal{T} which transforms an element of \mathcal{T} with support Ω into an element with support $\Omega + \omega$. As \mathfrak{S} is a differential algebra automorphism, Δ and $\dot{\Delta}_{\omega}$ commute with $\frac{d}{dz}$. Furthermore, $\Delta_{\omega} := e^{\omega/z} \dot{\Delta}_{\omega}$ is a derivation of \mathcal{S} . We have

$$\Delta_{\omega} = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sum_{\omega'' \in (0, \infty)^n: |\omega''| = \omega} S_{\omega''}.$$

For further details we refer the reader to [7, 12].

Definition 5.8. For all $\alpha > 0$, ρ_{α} will denote the ‘change of variable’: $\rho_{\alpha} f(z) = f(z^{\alpha})$. We put: $\mathfrak{S}_{\alpha} = \rho_{\alpha} \mathfrak{S} \rho_{\alpha}^{-1}$, $\dot{\Delta}_{\omega}^{\alpha} = \rho_{\alpha} \dot{\Delta}_{\omega} \rho_{\alpha}^{-1}$ and $\Delta_{\omega}^{\alpha} = \rho_{\alpha} \Delta_{\omega} \rho_{\alpha}^{-1}$. Obviously,

$$\dot{\Delta}_{\omega}^{\alpha} = e^{-\omega z^{-\alpha}} \Delta_{\omega}^{\alpha}.$$

Let $r \in \mathbf{N}$, let $\mathbf{k} = (k_1, \dots, k_r)$, where $0 < k_1 < \dots < k_r < k_{r+1} = \infty$ and let $\mathbf{d} = (d_1, \dots, d_r) \in \{+, -\}^r$. By $\mathcal{S}_{\mathbf{k}; \mathbf{d}}$ we denote the set of all $f \in \rho_{k_1} \mathcal{S}$ with the following property:

For all $n \in \mathbf{N}$ and all $\omega = (\omega_1, \dots, \omega_n) \in \Omega^n(\rho_{k_1}^{-1} f)$, and all $j \in \{1, \dots, r\}$, there exist quasi-functions $f_{\omega, j} \in \mathcal{Q}_{k_{j+1}}^{< k_1} (I_j^{d_j})$, such that

$$f_{\omega, j} \pmod{\mathcal{A}^{\leq -k_j}} = f_{\omega, j-1}|_{I_j^{d_j}}$$

where $f_{\omega, 0} = \rho_{k_1} S_{\omega}(\rho_{k_1}^{-1} f)$.

By $\mathcal{T}_{\mathbf{k}; \mathbf{d}}$ we denote the set of all $f \in \rho_{k_1} \mathcal{T}$, $f = \sum_{\omega \in \mathbf{C}} e^{-\omega/z^{k_1}} f_{\omega}$, with the property that $f_{\omega} \in \mathcal{S}_{\mathbf{k}; \mathbf{d}}$ for all $\omega \in \mathbf{C}$. Note that $f_{\omega} = 0$ unless $\omega \in \Omega^0(\rho_{k_1}^{-1} f)$. We call $\Omega^0(\rho_{k_1}^{-1} f)$ the support of f .

It is easily verified that $\mathfrak{S}_{k_1}|_{\mathcal{T}_{\mathbf{k}; \mathbf{d}}}$ is again a differential algebra automorphism.

Application.

Consider the D.E. $Dy = 0$, where D is a linear differential operator of order n , with coefficients in $\mathbf{C}\{z\}$. It has a formal integral of the form:

$$\Phi(u; z) = \Phi(u_1, \dots, u_n; z) = \sum_{l=1}^n u_l e^{q_l(z)} z^{\rho_l} \hat{h}_l$$

where $u \in \mathbf{C}^n$, $\rho_l \in \mathbf{C}$, $q_l \in z^{-1/p} \mathbf{C}[z^{-1/p}]$, and $\hat{h}_l \in \mathbf{C}[[z^{1/p}]][\log z]$ for some $p \in \mathbf{N}$. Let $k_1 < \dots < k_r$ denote the levels of (D) , i.e. the values of $\frac{1}{p} \deg(q_l - q_m)$, where $l, m \in \{1, \dots, n\}$ such that $q_m \not\equiv q_l$. According to Theorem 1.4, \hat{h}_l is multi-summable in every multi-direction $\mathbf{d} = (d_1, \dots, d_r) \in \{+, -\}^r$. Thus, for every $j \in \{1, \dots, r\}$, there is a quasi-function $h_{l,j}^{\mathbf{d}} \in \mathcal{Q}_{k_{j+1}}^{<k_1}(I_j^{d_j})$ such that $h_{l,j}^{\mathbf{d}} \pmod{\mathcal{A}^{\leq -k_j}} = h_{l,j-1}^{\mathbf{d}}|_{I_j^{d_j}}$ and $h_{l,1}^{\mathbf{d}} \pmod{\mathcal{A}^{\leq -k_1}} = J^{-1}(\hat{h}_l)|_{I_1^{d_1}}$.

Proposition 5.9. *Let $r \in \mathbf{N}$, $0 < k_1 < \dots < k_{r+1} = \infty$. Let $i \in \{1, \dots, r\}$ and let $\mathbf{d}, \mathbf{d}' \in \{+, -\}^r$ such that $d_j = d'_j$ for all $j \neq i$, $d_i = -d'_i$. For each $j \in \{1, \dots, r\}$, let $I_j := I_j^{d_j}$ and $I'_j := I_j^{d'_j}$. Suppose that there exist $(y_1^1, \dots, y_r^1) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{<k_1}(I'_1, \dots, I'_r)$ and $(y_1^2, \dots, y_r^2) \in \mathcal{Q}_{(k_2, \dots, k_{r+1})}^{<k_1}(I_1, \dots, I_r)$ with the following properties:*

- (i) $(y_1^2 - y_1^1) \pmod{\mathcal{A}^{\leq -k_1}} = 0$
- (ii) $Dy_r^1 = Dy_r^2$.

For all $l \in \{1, \dots, n\}$, let $q_l = -\omega_l z^{-\kappa_l} + \tilde{q}_l$, where $\tilde{q}_l \in \mathbf{C}[z^{-1/p}]$, $\deg \tilde{q}_l < \deg q_l$ if $q_l \not\equiv 0$, otherwise $\omega_l = \kappa_l = 0$. There exist $u_l \in \mathbf{C}$ such that, for all $j \geq i$,

$$y_j^2 - y_j^1 = \sum_{l: \kappa_l = k_i, \omega_l > 0} u_l e^{q_l(z)} z^{\rho_l} h_{l,j}^{\mathbf{d}}.$$

Proof. Suppose $i < r$. According to Lemma 2.14, $y_j^2 - y_j^1 \in \mathcal{Q}_{k_{j+1}}^{\leq -k_i}(I_j)$ for all $j > i$, whereas $y_i^2 - y_i^1 \in \mathcal{Q}_{k_{i+1}}^{\leq -k_i}((-\frac{\pi}{2k_i}, \frac{\pi}{2k_i}))$. On the other hand, there exist complex numbers u_1, \dots, u_n such that

$$y_r^2 - y_r^1 = \sum_{l=1}^n u_l e^{q_l(z)} z^{\rho_l} h_{l,r}^{\mathbf{d}}.$$

As $y_r^2 - y_r^1 \in \mathcal{A}^{\leq -k_i}(I_r)$ and e^{q_l} is of order κ_l , it follows that $u_l = 0$ for all l such that $\kappa_l < k_i$. From the fact that $\cos(\arg \omega_l - \kappa_l \arg z)$ changes sign on I_r if $\kappa_l = k_r$ we infer that $u_l = 0$ for all l such that $\kappa_l = k_r$ as well.

Consequently,

$$\begin{aligned} y_{r-1}^2 - y_{r-1}^1|_{I_r} &= \sum_{l:k_i \leq \kappa_l < k_r} u_l e^{q_l(z)} z^{\rho_l} h_{l,r}^{\mathbf{d}} \pmod{\mathcal{A}^{\leq -k_r}} \\ &= \sum_{l:k_i \leq \kappa_l < k_r} u_l e^{q_l(z)} z^{\rho_l} h_{l,r-1}^{\mathbf{d}}|_{I_r}. \end{aligned}$$

In view of the quasi-analyticity of the sheaf $\mathcal{Q}_{k_r}^{<k_r}$ (Proposition 2.2), this implies that

$$y_{r-1}^2 - y_{r-1}^1 = \sum_{l:k_i \leq \kappa_l < k_r} u_l e^{q_l(z)} z^{\rho_l} h_{l,r-1}^{\mathbf{d}}.$$

By means of induction on $r - j \in \{0, \dots, r - i\}$ one proves that $u_l = 0$ for all l such that $\kappa_l \neq k_i$, and

$$y_i^2 - y_i^1 = \sum_{l:\kappa_l = k_i} u_l e^{q_l(z)} z^{\rho_l} h_{l,i}^{\mathbf{d}}.$$

Noting that $\cos(\arg \omega_l - \kappa_l \arg z)$ changes sign on $(-\frac{\pi}{2k_i}, \frac{\pi}{2k_i})$ if $\kappa_l = k_i$ and $\arg \omega_l \notin 2\pi\mathbf{Z}$, we conclude that $u_l = 0$ unless $\omega_l > 0$. The proof for the case that $i = r$ is similar. \square

For every $\mathbf{d} \in \{+, -\}^r$ and every $l \in \{1, \dots, n\}$, $h_{l,r}^{\mathbf{d}}$ satisfies a linear D.E. of order n , with formal solutions $e^{q_{ml}} z^{\rho_{ml}} \hat{h}_m$, where $q_{ml} = q_m - q_l$, $\rho_{ml} = \rho_m - \rho_l$, $m = 1, \dots, n$. We fix a multi-direction \mathbf{d} and write $h_{l,j} := h_{l,j}^{\mathbf{d}}$ for all $j \in \{1, \dots, r\}$. As \hat{h}_l is multi-summable in every multi-direction $\in \{+, -\}^r$, so in particular in every multi-direction $\in \{+, -\}^r$ whose first $j-1$ components coincide with those of \mathbf{d} , there exists, for every $j \in \{1, \dots, r\}$, an element $h_{l,j}^{\pm}$ of $\mathcal{Q}_{k_{j+1}}^{<k_1}(I_j^{\pm})$ with the property that

$$h_{l,j}^{\pm} \pmod{\mathcal{A}^{\leq -k_j}} = h_{l,j-1}|_{I_j^{\pm}}.$$

Let $q_{ml} = -\omega_{ml} z^{-\kappa_{ml}} + \tilde{q}_{ml}$, where $\deg \tilde{q}_{ml} < \deg q_{ml}$ if $q_{ml} \neq 0$, otherwise $\omega_{ml} = \kappa_{ml} = 0$. From Proposition 5.9 it follows that

$$h_{l,j}^- - h_{l,j}^+ = \sum_{m:\kappa_{ml}=k_j, \omega_{ml}>0} e^{-\omega_{ml} z^{-k_j}} (u_{ml} e^{\tilde{q}_{ml}(z)} z^{\rho_{ml}} h_{m,j}^+)$$

where $u_{ml} \in \mathbf{C}$. This shows that $h_{l,j-1}|_{\left[-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right]} \in \rho_{k_j} \mathcal{S}^1$ and

(32)

$$\rho_{k_j} S_{\omega} \rho_{k_j}^{-1} h_{l,j-1}|_{\left[-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right]} = \sum_{m:\kappa_{ml}=k_j, \omega_{ml}=\omega} u_{ml} e^{\tilde{q}_{ml}(z)} z^{\rho_{ml}} h_{m,j-1}|_{\left[-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right]}.$$

Let $\mathbf{k}^j = (k_j, \dots, k_r)$ and $\mathbf{d}^j = (d_j, \dots, d_r)$. It is easily seen that $h_{l,j-1}|_{\left[-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right]} \in \mathcal{S}_{\mathbf{k}^j; \mathbf{d}^j}$. It can also be considered to be an element of $\mathcal{T}_{\mathbf{k}^j; \mathbf{d}^j}$ with support $\{0\}$. Let $\omega > 0$ and define

$$J_{l,\omega}^{(j)} := \{m \in \{1, \dots, n\} : \deg(q_{ml} + \omega z^{-k_j}) < pk_j\}$$

(here $q_{ml} + \omega z^{-k_j}$ is considered a polynomial in $z^{-1/p}$) and

$$J_{l,\omega}^{(j,s)} = \{(m_1, \dots, m_s) \in \{1, \dots, n\}^s : \kappa_{m_1 l} = \dots = \kappa_{m_s l} = k_j, \\ 0 < \omega_{m_1 l} < \dots < \omega_{m_s l} < \omega\}.$$

From (31), (32) and Definition 5.8 we deduce that

$$(33) \quad \dot{\Delta}_{\omega}^{k_j} h_{l,j-1}|_{\left[-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right]} = \sum_{m \in J_{l,\omega}^{(j)}} A_{l,m}(\omega) e^{q_{ml}(z)} z^{\rho_{ml}} h_{m,j-1}|_{\left[-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right]}$$

where

$$A_{l,m}(\omega) = u_{ml} + \sum_{s=1}^{\infty} \frac{(-1)^s}{s+1} \sum_{(m_1, \dots, m_s) \in J_{l,\omega}^{(j,s)}} u_{m_1 l} u_{m_2 m_1} \dots u_{m m_s}.$$

Defining

$$\Phi^{(j)}(u; z) = \sum_{l=1}^n u_l e^{q_l(z)} z^{\rho_l} h_{l,j-1}|_{\left[-\frac{\pi}{2k_j}, \frac{\pi}{2k_j}\right]}$$

and extending $\dot{\Delta}_{\omega}^{k_j}$ to $\mathcal{T}_{\mathbf{k}^j; \mathbf{d}^j}[e^{q_1}, \dots, e^{q_n}]$, we can summarize the above relations in one formula, for each $j \in \{1, \dots, r\}$ (“the **bridge equation** of level k_j ”):

$$(34) \quad \dot{\Delta}_{\omega}^{k_j} \Phi^{(j)}(u; z) = A_{\omega}^{(j)}(u) \nabla_u \Phi^{(j)}(u; z)$$

where $A_{\omega}^{(j)}(u)$ is a row vector with components

$$A_{\omega,m}^{(j)}(u) = \sum_{l: \deg(q_{ml} + \omega z^{-k_j}) < pk_j} A_{l,m}(\omega) u_l, \quad m = 1, \dots, n.$$

The numbers $A_{l,m}(\omega)$ depend on (the first $j-1$ components of) the multi-direction \mathbf{d} . As $h_{l,j-1}$ is uniquely determined by \hat{h}_l and d_1, \dots, d_{j-1} , we can define operators $\dot{\Delta}_{\omega, d_1, \dots, d_{j-1}}^{k_j}$ acting on formal power series and replace (34) with

$$\dot{\Delta}_{\omega, d_1, \dots, d_{j-1}}^{k_j} \Phi(u; z) = A_{\omega, d_1, \dots, d_{j-1}}(u) \nabla_u \Phi(u; z).$$

The numbers $A_{l,m}(\omega)$ are analytic invariants of the differential equation.

The bridge equation is due to J. Ecalle, cf. [8], [9]. For a different approach based on differential Galois theory we refer to a paper by J. Martinet and J.-P. Ramis [22].

Example 5.10. Let $D = D_1 D_2 D_3$ where $D_1 = (z \frac{d}{dz} - 1)$, $D_2 = (z^2 \frac{d}{dz} - 1)$ and $D_3 = (z^3 \frac{d}{dz} - 1)$. All solutions of the equation $D_1 y = 0$ are multiples of the function $y(z) = z$. Therefore, y is a solution of $D_1 D_2 y = 0$ if and only if $D_2 y = az$ for some $a \in \mathbf{C}$. In [23] it is shown that D_2 and D_3 define isomorphisms of $\mathbf{C}\{z\}_1$ and $\mathbf{C}\{z\}_2$, respectively. Hence the equation

$$\left(z^2 \frac{d}{dz} - 1\right) y = z$$

has a unique formal power series solution \hat{h} , which is 1-summable. The sum h^\pm in the direction \pm can be represented by the Laplace integral

$$h^\pm(z) = \int_{l_\pm} \frac{e^{-\zeta/z}}{\zeta - 1} d\zeta$$

where l_\pm is a half line from O to ∞ in a direction θ such that $\pm\theta \in (0, 2\pi)$. Thus all formal solutions of the homogeneous equation $(D_1 D_2)$ have the form $a\hat{h} + be^{-1/z}$, where $a, b \in \mathbf{C}$. Let \hat{h}_2 and \hat{h}_3 denote the (unique) formal power series solutions of $D_3(e^{-1/z}y) = e^{-1/z}$, or, equivalently, of

$$(35) \quad \left(z^3 \frac{d}{dz} - 1 + z\right) y = 1$$

and $D_3 y = \hat{h}$, respectively. The equation $Dy = 0$ has a formal integral of the form

$$\Phi(u; z) = u_1 e^{-\frac{1}{2}z^{-2}} + u_2 e^{-z^{-1}} \hat{h}_2(z) + u_3 \hat{h}_3(z).$$

It has two levels: $k_1 = 1$ and $k_2 = 2$. One easily verifies that

$$J_{3,1}^{(1)} = \{2\}, \quad J_{2, \frac{1}{2}}^{(2)} = \{1\}, \quad J_{3, \frac{1}{2}}^{(2)} = \{1\}$$

and $J_{l,\omega}^{(j)} = \emptyset$ otherwise. Hence there exist complex numbers $A_{3,2}$, $A_{2,1}$, $A_{3,1,+}$ and $A_{3,1,-}$ such that

$$\dot{\Delta}_1^1 \Phi(u; z) = (0, u_3 A_{3,2}, 0) \frac{\partial}{\partial u} \Phi(u; z)$$

and

$$\dot{\Delta}_{\frac{1}{2}, \pm}^2 \Phi(u; z) = (u_2 A_{2,1} + u_3 A_{3,1,\pm}, 0, 0) \frac{\partial}{\partial u} \Phi(u; z).$$

(Note that the 2-summability of \hat{h}_2 implies that $A_{2,1}$ is independent of d_1 .) In this simple example the invariants $A_{3,2}$, $A_{2,1}$, $A_{3,1,+}$ and $A_{3,1,-}$ can be

easily calculated. The difference between the 1-sums h^+ and h^- of \hat{h} in the directions $+$ and $-$ is

$$h^-(z) - h^+(z) = 2\pi i e^{-\frac{1}{z}}.$$

This implies that $\dot{\Delta}_1^1 \hat{h} = 2\pi i e^{-\frac{1}{z}}$. Hence we deduce the relation

$$\left(z^3 \frac{d}{dz} - 1\right) \dot{\Delta}_1^1 \hat{h}_3 = \dot{\Delta}_1^1 \left(z^3 \frac{d}{dz} - 1\right) \hat{h}_3 = \dot{\Delta}_1^1 \hat{h} = 2\pi i e^{-\frac{1}{z}}.$$

It follows that $\dot{\Delta}_1^1 \hat{h}_3 = 2\pi i e^{-\frac{1}{z}} \hat{h}_2$ and thus $A_{3,2} = 2\pi i$.

It can be shown that the 2-sums h_2^+ and h_2^- of \hat{h}_2 in the directions $+$ and $-$ are given by

$$h_2^\pm(z) = e^{-\frac{1}{2}z^{-2}+z^{-1}} \int_{\gamma^\pm(z)} e^{\frac{1}{2}\zeta^{-2}-\zeta^{-1}} \zeta^{-3} d\zeta$$

where $\gamma^\pm(z)$ is a path from O to z , tangent at O to a half line with direction θ such that $\pm\theta \in (\frac{\pi}{4}, \frac{3\pi}{4})$ (the expression in the right-hand side of the above formula represents the unique solution of (35) which is bounded on the half line $\arg z = \pm\frac{\pi}{2}$). It is easily seen that

$$h_2^-(z) - h_2^+(z) = i\sqrt{2\pi} e^{-\frac{1}{2}z^{-2}+z^{-1}-\frac{1}{2}}$$

and thus $A_{2,1} = i\sqrt{\frac{2\pi}{e}}$.

For any multi-direction $\mathbf{d} \in \{+, -\}^2$ let $h_3^{\mathbf{d}}$ denote the function defined by

$$h_3^{\mathbf{d}}(z) = e^{-\frac{1}{2}z^{-2}} \int_{\gamma^{\mathbf{d}_2}(z)} e^{\frac{1}{2}\zeta^{-2}} \zeta^{-3} h^{d_1}(\zeta) d\zeta.$$

By means of elementary asymptotic methods (cf. [26]) it can be shown that

$$h_3^{(+,+)} \in \mathcal{A}^{(1)}\left(\left(-\frac{\pi}{4}, \frac{5\pi}{4}\right)\right), \quad h_3^{(+,-)} \in \mathcal{A}^{(1)}\left(\left(-\frac{\pi}{2}, \frac{\pi}{4}\right)\right),$$

$$h_3^{(-,+)} \in \mathcal{A}^{(1)}\left(\left(-\frac{\pi}{4}, \frac{\pi}{2}\right)\right), \quad h_3^{(-,-)} \in \mathcal{A}^{(1)}\left(\left(-\frac{5\pi}{4}, \frac{\pi}{4}\right)\right).$$

Moreover,

(36)

$$h_3^{(d_1,-)}(z) - h_3^{(d_1,+)}(z) = e^{-\frac{1}{2}z^{-2}} \int_{\Gamma} e^{\frac{1}{2}\zeta^{-2}} \zeta^{-3} h^{d_1}(\zeta) d\zeta \in \mathcal{A}^{\leq -2}\left(\left(-\frac{\pi}{4}, \frac{\pi}{4}\right)\right)$$

where Γ is a closed contour tangent at O to half lines with directions θ and $-\theta$, for some $\theta \in (\frac{\pi}{4}, \frac{3\pi}{4})$. Hence we infer that $\{h_3^{(+,-)}, h_3^{(+,+)}\}$ represents an element $h_{3,1}^+$ of $\mathcal{A}^{(1)}/\mathcal{A}^{\leq -2}((-\frac{\pi}{2}, \frac{5\pi}{4}))$ and

$$h_{3,1}^+|_{(-\frac{\pi}{2}, \frac{\pi}{4})} = h_3^{(+,-)} \pmod{\mathcal{A}^{\leq -2}}.$$

Similarly, one proves that $\{h_3^{(-,-)}, h_3^{(-,+)}\}$ represents an element $h_{3,1}^-$ of $\mathcal{A}^{(1)}/\mathcal{A}^{\leq -2}((-\frac{5\pi}{4}, \frac{\pi}{2}))$ with the property that

$$h_{3,1}^-|_{(-\frac{\pi}{4}, \frac{\pi}{2})} = h_3^{(-,+)} \pmod{\mathcal{A}^{\leq -2}}.$$

Hence it follows that $h_3^{\mathbf{d}}$ is the $(1, 2)$ -sum of \hat{h}_3 in the multi-direction \mathbf{d} . From (36) we deduce that

$$A_{3,1,\pm} = \int_{\Gamma} e^{\frac{1}{2}\zeta^{-2}} \zeta^{-3} h^{\pm}(\zeta) d\zeta.$$

Example 5.11. Let (D) be a third order homogeneous linear differential equation with formal integral

$$\Phi(u; z) = u_1 e^{-z^{-2}-z^{-1}} \hat{h}_1(z) + u_2 e^{-z^{-1}} \hat{h}_2(z) + u_3 \hat{h}_3(z)$$

where $\hat{h}_1 \equiv 1$, $\hat{h}_2 = -\widehat{CH}_2(e^{-z^{-2}})$ and $\hat{h}_3 = \widehat{CH}_1(e^{-z^{-1}} CH_2^+(e^{-z^{-2}}))$. \hat{h}_2 is 2-summable in the directions $+$ and $-$ with sums $h_2^+ = -CH_2^+(e^{-z^{-2}})$ and $h_2^- = -CH_2^-(e^{-z^{-2}})$, respectively. Moreover, $h_2^-(z) - h_2^+(z) = e^{-z^{-2}}$. Hence it follows that $\Delta_{\omega}^2 \hat{h}_2 = 0$ for all $\omega \neq 1$, whereas $\Delta_1^2 \hat{h}_2 \equiv 1$. Now consider \hat{h}_3 . Let $h_{j,0} = J^{-1}(\hat{h}_j)$, $j = 1, 2, 3$, and let $f := h_{3,0}|_{[-\frac{\pi}{2}, \frac{\pi}{2}]}$. f can be represented by the restriction to $[-\frac{\pi}{2}, \frac{\pi}{2}]$ of

$$\{-CH_1^-(e^{-z^{-1}} h_2^+), -CH_1^+(e^{-z^{-1}} h_2^+)\}.$$

Let f^+ denote the element of $\mathcal{A}^{(1)}/\mathcal{A}^{< -1}((-\frac{\pi}{2}, \frac{\pi}{2}))$ with representative

$$\{-CH_1^-(e^{-z^{-1}} h_2^+) - e^{-z^{-1}} h_2^-, -CH_1^+(e^{-z^{-1}} h_2^+)\}$$

and let f^- denote the element of $\mathcal{A}^{(1)}/\mathcal{A}^{< -1}([-\frac{\pi}{2}, \frac{\pi}{2}))$ with representative

$$-CH_1^-(e^{-z^{-1}} h_2^+).$$

Obviously, $f^+ \pmod{\mathcal{A}^{\leq -1}} = f|_{(-\frac{\pi}{2}, \frac{\pi}{2})}$ and $f^- \pmod{\mathcal{A}^{\leq -1}} = f|_{[-\frac{\pi}{2}, \frac{\pi}{2})}$. It is easily seen that $f^- - f^+$ is the element of $\mathcal{A}^{\leq -1}/\mathcal{A}^{< -1}((-\frac{\pi}{2}, \frac{\pi}{2}))$ represented by $\{e^{-z^{-1}} h_2^-, e^{-z^{-1}} h_2^+\}$. This shows that $\Delta_{\omega}^1 h_{3,0}|_{[-\frac{\pi}{2}, \frac{\pi}{2}]} = 0$ for all $\omega \neq 1$, whereas

$$\Delta_1^1 h_{3,0}|_{[-\frac{\pi}{2}, \frac{\pi}{2}]} = h_{2,0}|_{[-\frac{\pi}{2}, \frac{\pi}{2}]}.$$

Furthermore, we have

$$(37) \quad (CH_1^-(e^{-z^{-1}} h_2^+) + e^{-z^{-1}} h_2^-) - CH_1^+(e^{-z^{-1}} h_2^+) = e^{-z^{-2}-z^{-1}}.$$

Let $h_{3,1}^-$ and $h_{3,1}^+$ be the elements of $\mathcal{A}^{(1)}/\mathcal{A}^{\leq -2}([-\frac{\pi}{2}, \frac{\pi}{2}))$ and $\mathcal{A}^{(1)}/\mathcal{A}^{\leq -2}((-\frac{\pi}{2}, \frac{\pi}{2}])$, represented by $-CH_1^-(e^{-z^{-1}} h_2^+)$ and $\{-CH_1^-(e^{-z^{-1}} h_2^+) - e^{-z^{-1}} h_2^-, -CH_1^+(e^{-z^{-1}} h_2^+)\}$, respectively. Now, $(h_{3,1}^-, -CH_1^-(e^{-z^{-1}} h_2^+))$ is the $(1, 2)$ -sum of \hat{h}_3 in the direction $(-, 0)$, $(h_{3,1}^+, -CH_1^-(e^{-z^{-1}} h_2^+) - e^{-z^{-1}} h_2^-)$ is

the $(1, 2)$ -sum of \hat{h}_3 in the direction $(+, -)$ and $(h_{3,1}^+, -CH_1^+(e^{-z^{-1}}h_2^+))$ is the $(1, 2)$ -sum of \hat{h}_3 in the direction $(+, +)$. From (37) we deduce that $\Delta_\omega^2 h_{3,1}^-|_{[-\frac{\pi}{4}, \frac{\pi}{4}]} = 0$ for all $\omega > 0$, whereas $\Delta_\omega^2 h_{3,1}^+|_{[-\frac{\pi}{4}, \frac{\pi}{4}]} = 0$ for all $\omega \neq 1$ and $\Delta_1^2 h_{3,1}^+|_{[-\frac{\pi}{4}, \frac{\pi}{4}]} = -e^{-z^{-1}}$.

Combining the above results and applying them to the formal integral we find

$$\begin{aligned}\dot{\Delta}_1^1 \Phi(u; z) &= (0, u_3, 0) \frac{\partial}{\partial u} \Phi(u; z), \\ \dot{\Delta}_{1,-}^2 \Phi(u; z) &= (u_2, 0, 0) \frac{\partial}{\partial u} \Phi(u; z)\end{aligned}$$

and

$$\dot{\Delta}_{1,+}^2 \Phi(u; z) = (u_2 - u_3, 0, 0) \frac{\partial}{\partial u} \Phi(u; z).$$
